

A Comprehensive Overview and Survey of O-RAN: Exploring Slicing-aware Architecture, Deployment Options, and Use Cases

Khurshid Alam¹, Mohammad Asif Habibi², Matthias Tammen³, Dennis Krummacker⁴,

Walid Saad⁵ (Fellow, IEEE), Marco Di Renzo⁶ (Fellow, IEEE), Tommaso Melodia⁷ (Fellow, IEEE), Xavier Costa-Pérez⁸ (Senior Member, IEEE), Mérouane Debbah⁹ (Fellow, IEEE), Ashutosh Dutta¹⁰ (Fellow, IEEE), and Hans D. Schotten¹¹ (Member, IEEE)

Abstract—Open-radio access network (O-RAN) seeks to establish principles of openness, programmability, automation, intelligence, and hardware-software disaggregation with interoperable interfaces. It advocates for multi-vendorism and multi-stakeholderism within a cloudified and virtualized wireless infrastructure, aimed at enhancing the deployment, operation, and maintenance of RAN architecture. This enhancement promises increased flexibility, performance optimization, service innovation, energy efficiency, and cost efficiency in fifth-generation (5G), sixth-generation (6G), and future networks. One of the key features of the O-RAN architecture is its support for network slicing, which entails interaction with other slicing domains within a mobile network, notably the transport network (TN) domain and the core network (CN) domain, to realize end-to-end (E2E) network slicing. The study of this feature requires exploring the stances and contributions of diverse standards development organizations (SDOs). In this context, we note that despite the ongoing industrial deployments and standardization efforts, the research and standardization communities have yet to comprehensively address network slicing in O-RAN. To address this gap, this survey paper provides a comprehensive exploration of network slicing in O-RAN through an in-depth review of specification documents from O-RAN Alliance and research papers from leading industry and academic institutions. The paper commences with an overview of the ongoing standardization efforts and open-source contributions associated with O-RAN, subsequently delving into the latest O-RAN architecture

with an emphasis on its slicing aspects. Further, the paper explores deployment scenarios for network slicing within O-RAN, examining options for the deployment and orchestration of O-RAN and TN network slice subnets. It discusses the slicing of the underlying infrastructure, encompassing both TNs and compute resource slicing. Finally, the paper provides a summary of various use cases related to O-RAN slicing.

Index Terms—5G, 6G, Disaggregation, Management and Orchestration, Intelligence, Near-RT RIC, Network Slicing, NFV-MANO, Non-RT RIC, O-Cloud Site, O-RAN, Open Interfaces, Openness, RAN Architecture, RAN Slicing, RIC, SMO Framework, TN Slicing

I. INTRODUCTORY REMARKS

THE radio access network (RAN) serves as a critical domain within a cellular network, responsible for enabling wireless connectivity between the user equipment (UE) and base station across a specified geographical footprint. It employs heterogeneous radio access technologies (RATs) to ensure efficient data transmission both in the upstream and downstream directions [1]. The RAN's architectural evolution was shaped by several key factors, including the ever-increasing number of UEs, the growing complexity and diversity of wireless access technologies, the relentless pursuit of enhanced network performance (such as higher data rates, lower latency, broader coverage, etc.), embracing emerging trends such as virtualization and cloudification, and the escalating demand for diverse communication and beyond-communication services over the past decades [2]–[5]. This continuous evolution, exemplified by its transformation from fourth-generation (4G) to fifth-generation (5G) and now towards sixth-generation (6G), has been instrumental in enabling a wide range of transformative applications, services, and use cases [6]–[8].

Introduced in 4G, the distributed RAN (D-RAN) architecture proposed a separation of the radio and baseband processing functionalities into two distinct entities: the baseband unit (BBU) and remote radio head (RRH) [9]. However, these components were situated at the same location within the same cellular network site and connected via an internal interface within the corresponding base station [2]. Subsequently, the centralized RAN (C-RAN) architecture has emerged, introducing a significant departure from traditional RAN architectures by decoupling the BBU and RRH [1], [2]. In this approach, the BBU is physically relocated to a centralized data center (DC), enabling centralized control and optimization of multiple RRHs through a high-speed fronthaul (FH) interface utilizing the common public radio interface

(CPRI) technologies [9], [10]. The emergence of D-RAN and C-RAN architectures marked significant advancements in the development and deployment of numerous RAN architectures and RATs, paving the way for further innovations in 4G and beyond [1], [11].

The advent of 5G heralded a paradigm shift in RAN architecture, driving substantial transformations to harness the diverse demands of a wide range of use cases and industrial applications [2]. The goal was to establish a distributed, programmable, and adaptable RAN architecture, equipped to seamlessly accommodate the evolving needs of emerging vertical markets [12]. Aiming to enhance flexibility and adaptability, the 3rd Generation Partnership Project (3GPP) proposed the next-generation RAN (NG-RAN) as the 5G RAN architecture [13]. The NG-RAN comprises a number of base stations known as the next generation NodeB (gNB). The NG-RAN introduces a split of the gNB, placing higher protocol layers under the control of the centralized unit (CU) and delegating responsibility for lower protocol stacks to the distributed unit (DU) [14], [15]. Building upon the 3GPP-defined gNB, the Open RAN (O-RAN) Alliance proposed a further distribution of DU functionalities into two distinct entities: DU and radio unit (RU). With this approach, the gNB now encompasses CU, DU, and RU [16]. This architectural improvement introduced significant scalability, enabling a single CU to effectively manage multiple DUs, while each DU could seamlessly connect to multiple RUs, responsible for the efficient transmission and reception of radio signals to and from 5G UEs.

One of the features of the NG-RAN is its seamless integration with cloud-native and virtualized environments, enabling the deployment of CU and DU on commercial off-the-shelf (COTS) hardware within a cloudified and virtualized infrastructure [16]. Despite the increasing momentum towards virtualization and disaggregation in NG-RAN, the architecture has predominantly maintained a closed and proprietary approach, thereby constraining the flexibility and innovation potential it could otherwise provide [17], [18]. The NG-RAN components often embody complex proprietary designs developed and tailored by the respective network equipment manufacturers [19]. The interfaces connecting these components are engineered for peak performance, but they are exclusively compatible with the proprietary hardware of the specific manufacturer, hindering the prospects of multi-vendor interoperability [14], [20].

To foster open interfaces and facilitate multi-vendor interoperability, the O-RAN Alliance has proposed a groundbreaking industry initiative, the O-RAN architecture, aiming to revolutionize traditional NG-RAN [21]. This initiative seeks to replace closed and proprietary NG-RAN with open, interoperable, and cloud-driven systems. The O-RAN Alliance establishes the development of open standards and specifications, fostering compatibility and innovation amidst a diverse landscape of network equipment vendors [17]. Simultaneously, it embraces artificial intelligence (AI) and machine learning (ML) to revolutionize network automation and optimization through the RAN intelligent controller (RIC) [22]–[25]. To achieve an open and intelligent NG-RAN architecture for 5G and beyond, there is a need to deploy open interfaces between

NG-RAN components as well as to adopt software-defined networking (SDN) and network function virtualization (NFV) [26], [27]. In addition, the O-RAN architecture paves the way for realizing groundbreaking services and applications in cellular networks, enabling the deployment of network slicing, dynamic spectrum sharing, and resource sharing [20], [28]–[30].

Empowered by the O-RAN architecture, network slicing enables the creation of open slices, effectively partitioning a physical network into multiple virtualized networks that can operate simultaneously and independently [17]. Each virtualized network can be configured to match the specific requirements of diverse use cases, catering to the unique demands of 5G and beyond applications [31]. This specifically means that dedicated virtual network slices can be tailored to fulfill specific user needs [28], enabling the simultaneous provisioning of a diverse range of services while dynamically allocating network resources to match the individualized requirements of each slice [32]. In contrast to the rigid and inflexible *one size fits all* architectural solution, network slicing introduces a paradigm shift towards a more dynamic, flexible, and efficient approach to network optimization and resource allocation [33], [34].

Notwithstanding the above features of traditional RANs slicing, O-RAN brings several advantages to slicing. **(a)** With limited ability to customize resource allocation for specific slices, O-RAN's disaggregated architecture allows for more granular control. Different vendors can provide special hardware and software optimized for specific slice requirements. This allows for a more tailored approach to slicing. **(b)** Traditionally, creating slices with specific performance characteristics might require specific vendor equipment. O-RAN's open interfaces make it possible to mix and match components from different vendors as long as they comply with O-RAN standards. This allows operators to choose the best-in-breed solutions for each slice, potentially leading to cost savings and innovation. **(c)** To facilitate automated closed-loop control of the RAN, O-RAN introduces two RICs [22], [35]. The non-real-time RIC (Non-RT RIC) and near-real-time RIC (Near-RT RIC) in O-RAN enable the deployment of intelligent applications (rApps and xApps) tailored for slicing. These applications dynamically handle resources and enhance performance for slices in real-time, a task challenging with traditional RAN architectures [36]. **(d)** O-RAN facilitates automation in slicing through its open interfaces and standardized protocols. This allows for automated slice creation, configuration, and management, making the process faster and less error-prone compared to manual configuration in traditional RANs.

In addition, network slicing empowers mobile network operators (MNOs) to deliver services tailored to exacting requirements, facilitating the fulfillment of service level agreements (SLAs) with tenants [46]. This approach specifically addresses the heterogeneity of performance requirements and network functionalities by introducing standardized service types, defined by the 3GPP. These standardized service types, as of this writing, encompass enhanced mobile broadband (eMBB), ultra reliable low latency communication (URLLC), massive machine type communication (mMTC), high-performance ma-

TABLE I
COMPARING THE CONTRIBUTIONS OF OUR PAPER TO THE MOST RECENT STATE-OF-THE-ART OVERVIEW AND SURVEY PAPERS RELATED TO THE O-RAN.

Ref.	Year	Summary of Key Contributions
[15]	2020	<ul style="list-style-type: none"> • Overview of architectures for open and programmable 5G networks, with a particular focus on O-RAN • Extensive collection of recent open-source software and frameworks developed for the O-RAN architecture
[5]	2022	<ul style="list-style-type: none"> • Evolution of O-RAN through deployments, advancements, current initiatives, and standards activities • Exploration of O-RAN components, proposal of open-source solutions, and identify research challenges
[37]	2022	<ul style="list-style-type: none"> • Detailed exploration of O-RAN architecture, outlining its components and interfaces • Illumination of potential benefits and burgeoning market trends of O-RAN adoption in 5G and beyond
[26]	2022	<ul style="list-style-type: none"> • Presenting the deployment of O-RAN and the integration of AI/ML models into O-RAN architecture • Introducing an architecture that enables seamless end-to-end (E2E) data collection and real-time analytics

This paper	2024	<ul style="list-style-type: none"> • Offers a detailed exploration of the latest O-RAN architecture, open-source activities, and standardization efforts made by various standards development organizations (SDOs), with an emphasize on network slicing • Provides insights into the deployment scenarios for service management and orchestration (SMO) Framework to effectively manage and orchestrate O-RAN slice subnets and their corresponding resources • Explores the underlying infrastructure that hosts O-RAN network functions (NFs) and transport networks (TNs)

chine type communication (HMTc), and vehicle to everything (V2X) [16]. The number of these standardized service types is anticipated to expand significantly with the continuous advancement and deployment of communication and non-communication services in 5G, 6G, and beyond [6].

Despite the significant contributions of the 3GPP in RAN slicing, the O-RAN Alliance has also played a pivotal role in the intelligentization of open interfaces and components to support intelligent slicing within O-RAN [47]. The RIC [22], which serves as a robust platform for hosting slicing-aware applications, can train, host, and execute the AI/ML models to achieve intelligent O-RAN slicing. These models can predict and optimize traffic fluctuations based on a comprehensive set of defined metrics [12]. To fully realize the potential of slicing within an O-RAN, it is essential to foster a seamless unification between O-RAN and 3GPP standards at various levels [48]. This unification is crucial for addressing the

intricate challenges and complexities associated with RAN slicing across various domains of the two standards.

It is noteworthy that, while the O-RAN Alliance and 3GPP frameworks enable slicing in O-RAN, they do not directly address the virtualization aspects in O-RAN. To holistically encompass both the virtualized and physical dimensions of slicing within the O-RAN architecture, it is essential to establish harmonization among the 3GPP, O-RAN Alliance, and European Telecommunications Standards Institute (ETSI) frameworks. This harmonization of these three standardized frameworks is anticipated to pave the way for unified solutions for the realization of slicing within the O-RAN [48], enabling seamless delivery of various types of O-RAN slices.

A. Review of Survey and Overview Papers on O-RAN

Despite the remarkable progress and growing interest in 3GPP-defined RAN architectures and their slicing [49], [50],

realizing slicing in the O-RAN Alliance-defined architecture presents escalating challenges due to the stringent requirements of supporting open interfaces, seamless interoperability among components from diverse vendors, and the intricate interplay of multiple stakeholders within the management and network domains [17], [51]. Consequently, O-RAN slicing has recently emerged as a focal point of intense research interest within both the standardization and research communities.

Within the standardization community, the O-RAN Alliance is spearheading the role as a leading SDO that has been defining standards for O-RAN slicing. The specifications related to the network slicing have been published within the various working groups (WGs) of the O-RAN Alliance. We will delve into the pertinent specifications and contributions to O-RAN slicing in the subsequent chapters. However, the most recent specifications that lay the groundwork for O-RAN slicing, published by the WG 1, are accessible in [31], [52].

Within the research community, we have witnessed significant contributions to diverse research challenges. This encompasses aspects related to the management and orchestration of O-RAN slicing, designing xApps and rApps for O-RAN slices, and numerous optimization problems. Furthermore, several survey and overview papers related to the subject have been published by leading academic institutions. We present an up-to-date list of these papers, summarizing their major contributions to the O-RAN architecture (and, where applicable, to O-RAN slicing) in Table I.

B. The Primary Survey Gap in the Literature

Notwithstanding the fact that some of the earlier mentioned papers address network slicing and highlight its impact on the O-RAN, they lack a thorough analysis of O-RAN slicing. Specifically, there is a deficiency in presenting an accurate portrayal of the current scenario, exploring various proposed deployment options, and offering sufficient information on tightly integrating the different O-RAN components. In addition, there is a lack of literature on the seamless unification and interoperability among the O-RAN's components to ensure the successful development and deployment of various types of O-RAN slices. Therefore, according to our current understanding, there exists no comprehensive survey or overview paper in the literature that delves into the intricacies of network slicing in O-RAN in a comprehensive and thorough manner.

C. Goals and Contributions

To address the identified literature gap, this paper makes a significant contribution by offering a comprehensive survey and overview of network slicing in O-RAN. Specifically, the key contributions of this paper are as follows:

- Exploring open-source initiatives, standardization activities, and the design of experimental platforms for O-RAN.
- Focusing on the latest O-RAN architecture outlined by the O-RAN Alliance, with an additional emphasis on theoretical contributions from academic research and practical deployment from various leading industries.
- Providing a holistic view of the network slicing paradigm within O-RAN, we introduce the functional components and interfaces necessary for implementing network slicing within the O-RAN architecture.

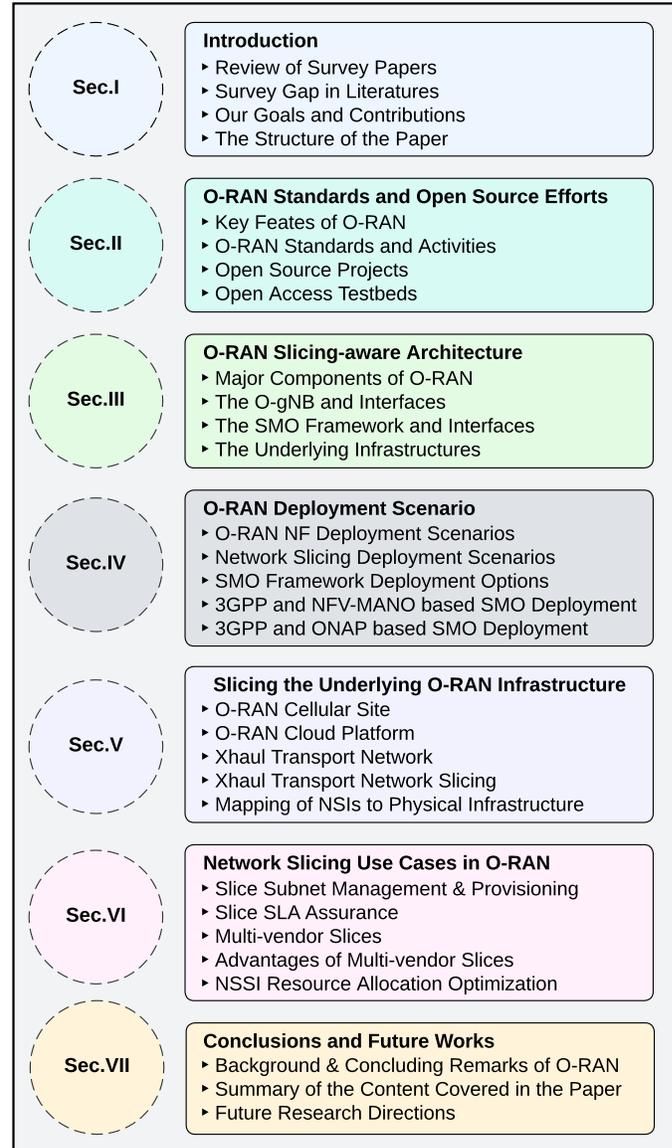

Fig. 1. Overview of the organization and structure of this survey paper. Each box represents one of the seven chapters of the paper, encapsulating their respective contributions and themes.

- Delving into the deployment scenarios of O-RAN slicing and the SMO Framework, we provide insights into a number of high-level use cases expected to be served by O-RAN's slicing-aware architecture.
- Discussing the NFs and TN elements, along with their management and orchestration, such as FH and mid-haul (MH), which constitute the O-RAN slice subnet. Additionally, this paper is addressing the aspects of the underlying infrastructure associated with TN slicing.

In Table I, we present a comparison between the contributions made in this article and those found in state-of-the-art survey articles on the subject.

D. The Organization of the Article

The rest of this survey paper is structured as follows: We begin with an overview of the open-source projects, activities, and their contributions, as well as the standardization efforts associated with O-RAN architecture in Section II. We then introduce the architectural components and open interfaces of O-

RAN slicing-aware architecture and highlight the features for O-RAN slicing in Section III. This section further includes discussions on O-RAN interactions with 3GPP-defined network components, service management, and service orchestration. In Section IV, we explain the various deployment scenarios for O-RAN deployment, O-RAN slicing, and SMO proposed by the O-RAN Alliance in relation to different use cases. Moving forward, Section V delves into the underlying infrastructure slicing within the O-RAN architecture, elaborating on the concepts of O-RAN cloud platform (O-Cloud) slicing, TN slicing, and TN slice orchestration. Section VI outlines high-level use cases that are expected to be prioritized and defined with support from the O-RAN community, particularly in relation to RAN slicing. Finally, Section VII offers a summary of our work, draws conclusions, and suggests potential directions for future research. To improve readability, an overview of the organization of this survey paper is illustrated in Figure 1.

II. ONGOING STANDARDIZATION EFFORTS AND OPEN SOURCE CONTRIBUTIONS TO THE O-RAN ARCHITECTURE

In this section, we explore, in detail, the fundamental features, characteristics, and implications of the O-RAN architecture. Additionally, we delve into ongoing open-source initiatives within the O-RAN ecosystem, alongside openly accessible experimental platforms specifically designed for developing the O-RAN components and interfaces. Furthermore, we provide an overview of state-of-the-art standardization contributions across various *de facto* and *de jure* SDOs associated with the O-RAN architecture. Our primary objective is to equip the inquisitive reader with a comprehensive understanding of the ongoing advancements associated with O-RAN.

A. Key Features and Principles of O-RAN

The primary motive behind O-RAN architecture for service providers is to diversify their vendor partnerships and avoid vendor lock-in, allowing the utilization of non-proprietary software and hardware components from various vendors [53]. Traditionally, RAN has been a proprietary and vertically integrated part of a mobile network, with tightly coupled hardware and software from a single vendor [17]. O-RAN seeks to change this paradigm by advocating for open interfaces and interoperability among RAN components. The O-RAN architecture prioritizes interoperability and flexibility through open standards, enabling network operators to choose equipment and software from different suppliers [40], [54]. This flexibility facilitates greater customization in network configuration, encouraging the involvement of second- and third-tier equipment manufacturers [53].

O-RAN not only establishes open interfaces but also enables unrestricted access to NG-RAN through AI-based control mechanisms, enhancing real-time sensing, proactive management, and dynamic responsiveness to radio resources [55], [56]. It supports programmable, disaggregated, virtualized, and interoperable tasks [16], enabling service providers to transition to a fully programmable, intelligent, autonomous, and multi-vendor RAN architecture for 5G, 6G, and beyond [53].

The integration of AI/ML models into the O-RAN facilitates the design of data-driven RICs, supporting service providers, vendors, and third parties with the onboarding of applications and use cases in an intelligent manner [48]. These applications and use cases aid in automating and optimizing O-RAN operations, reducing the total cost of ownership (TCO) for mobile carriers, and enhancing the quality of experience (QoE) and quality of service (QoS) of RAN services [57], [58].

The following bullet points sum up the main principles and characteristics of the O-RAN that service providers, network operators, and other stakeholders may find relevant.

- **Intelligent and Programmable Network:** O-RAN is designed to be intelligent and programmable, allowing for dynamic adjustments and optimizations in network operations. This flexibility enables the network to adapt to varying demands and scenarios efficiently [59].
- **Data Center Economics to RAN:** O-RAN brings the economic principles of DC to RAN, optimizing resource utilization and operational expenditure (OPEX) [54]. This approach enhances the efficiency of RAN infrastructure, aligning it with the cost-effective practices seen in DCs.
- **Lower TCO:** By leveraging DC economics and promoting efficiency, O-RAN aims to significantly reduce the overall TCO. This cost-effectiveness is achieved through streamlined operations and resource utilization [60].
- **Automation and Manageability:** O-RAN emphasizes automation and manageability, reducing the manual effort required for network operations. This not only improves efficiency but also enhances the reliability and consistency of network management tasks [59].
- **Faster Time to Market:** O-RAN facilitates a quicker time to market for deploying network solutions, enabling operators to roll out new services and features more rapidly. This speed in implementation is crucial for staying competitive in the rapidly evolving telecommunications landscape [61].
- **Agility of Innovation:** The architecture of the O-RAN fosters innovation agility, allowing for the swift development and integration of new technologies and features. This adaptability ensures that the network can keep pace with advancements and changing industry requirements [61].
- **Vendor Diversity:** O-RAN promotes vendor diversity, allowing network operators to choose from a variety of equipment and service providers. This flexibility enhances competition, encourages innovation, and provides network operators with options to tailor their networks according to specific requirements and preferences [60].
- **Open Source Software:** O-RAN leverages open-source software to provide reference implementations and encourage collaboration among industry participants [60].

The O-RAN Alliance – a consortium of telecom operators, vendors, and academic institutions – plays a crucial role in developing and promoting O-RAN standards. By adopting these principles, the industry aims to accelerate innovation, reduce deployment costs, and create a more dynamic and competitive marketplace for RAN solutions towards 5G, 6G,

and beyond mobile communication systems [17].

B. Network Slicing

Network slicing stands as a groundbreaking architectural solution. It facilitates the creation of multiple distinct virtual networks, or "slices," operating atop a shared physical infrastructure. This approach, heralded as a pivotal element of 5G, 6G, and beyond, introduces a wealth of possibilities to address diverse service demands and fully realize the capabilities of next-generation communication systems.

At its essence, network slicing involves partitioning the underlying physical network into discrete virtual networks, each finely configured to specific service requirements and performance criteria [62]. Each slice operates autonomously, offering tailored configurations of bandwidth, latency, security, and so forth [63]. This departure from traditional monolithic networks to a multi-sliced architecture empowers service providers to cater comprehensively, spanning from ultra-responsive industrial automation to high-throughput mobile broadband [64], [65].

An E2E network slice seamlessly traverses through all network domains, comprising RAN, TN, and core network (CN) segments [66]. Each slice is meticulously crafted to address the distinct needs and attributes of various services, ensuring logical separation. This isolation safeguards the integrity of individual network slices, preventing errors or malfunctions in one slice from impacting communication in others. Such isolation fosters the autonomy and reliability of each virtual network [67].

For every network slice, operators confidently commit dedicated resources, including computing power, bandwidth, QoS provisions, and other critical elements, guaranteeing optimal performance and service quality [68]. This assurance underscores the commitment to meeting the diverse demands of modern communication services while ensuring robustness and efficiency across the network landscape.

Despite the substantial progress made in E2E network slicing, persistent challenges remain in NG-RAN slicing [30], [64]. The complexity of NG-RAN slicing stems from the intricate task of balancing varying levels of isolation and resource sharing while tailoring the user plane (UP) and control plane (CP) for individual slices [69]. More specifically, these complexities stem from factors such as the need to balance the trade-off between utilization ratio and isolation level, establish harmonization among inter-RAN and intra-RAN slice resource allocation algorithms, and effectively manage inter-RAN and intra-RAN slice priorities [16]. In addition, the limited availability of radio resources demands highly efficient resource management to optimize network performance. Moreover, the introduction of features like bandwidth partitioning (BWP) and physical numerology in 5G new radio (NR) amplifies these complexities [70].

To address the aforementioned challenges, the 3GPP has provided guidelines in Release 17 for realizing RAN slicing in NG-RAN architecture. These guidelines encompass various aspects, including support for various QoSs, resource segregation, enforcement of SLA, and more [49]. 3GPP specifications further enhance flexibility by presenting options such as Layer

1, Layer 2, or medium access control (MAC)-based approaches for implementing RAN slicing [49], [71]. In addition, they also specify a management and orchestration framework for the efficient life cycle management of RAN slices over the NG-RAN architecture, as well as its interaction with other standardized frameworks for the realization of E2E network slicing [16].

C. O-RAN Standards and Activities

As of the present writing, numerous de facto and de jure organizations are actively engaged in establishing a software and hardware ecosystem in alignment with the principles of the O-RAN paradigm. These organizations participate in collaborative efforts within various SDOs. In this subsection, we delve into an exploration of these organizations and their contributions toward the realization of O-RAN.

1) *3GPP*: 3GPP does not directly establish standards for O-RAN. Nevertheless, various architectural components, NFs, management and orchestration frameworks, functional splits, interfaces, and other elements within the 3GPP-based RAN architecture have been extended by other SDOs to formulate standards for the O-RAN architecture. The 3GPP standards provide a comprehensive system definition for RAN architecture, distributed across several technical specification groups (TSGs).

During the 5G evolution, 3GPP considered eight different split variants and reached a consensus to establish two NG-RAN split architectures. We discussed these split options in our previous work in detail [16]. One of the two split architectures is high layer split (HLS), equivalent to option 2 from the 5G study, which involves dividing the BBU into CU and DU along with the separation of CP and UP functions for CU [40]. 3GPP further introduced the F1 interface that connects the CU to the DUs and the E1 interface to enable coordination between the CP and UP [72], [73].

The 3GPP-defined functional splits were established to promote the concept of disaggregating the standard protocol stack. This involves separating the processing of a specific layer within the protocol stack from the computing entity. This movement within the 3GPP framework is seen as the foundational step toward achieving genuine cellular interface and processing openness [41]. It has served as a pivotal catalyst for the development of subsequent O-RAN specifications which will be elaborated upon later in this section.

2) *O-RAN Alliance*: The O-RAN Alliance, established in 2018, is dedicated to the ambitious task of modernizing RAN architecture globally. The alliance's central mission revolves around steering the wireless communication industry towards a future characterized by openness, intelligence, virtualization, and seamless interoperability within the RAN. This transformative journey is underpinned by a shift towards virtualized network components, the adoption of white-box hardware, and the implementation of open interfaces facilitating communication between various RAN's software and hardware components [74].

To execute its vision, the O-RAN Alliance employs a structured approach outlined in the O-RAN specification, which is meticulously organized into several groups overseen by the

technical steering committee (TSC). The TSC plays a pivotal role in decision-making and provides essential guidance on O-RAN technical matters. It assumes the crucial responsibility of approving specifications before they undergo board approval and subsequent publication. Currently, the TSC comprises eleven technical WGs, five focus groups (FGs), a research group, an open-source community, and a minimum viable plan - committee (MVP-C). These diverse entities within the TSC collaborate to focus on specific aspects of the O-RAN architecture, contributing collectively to its development and deployment. For a concise overview of the objectives and areas of focus within these divisions, refer to Table II.

3) *Telecom Infra Project*: The telecom infra project (TIP) is a global collaboration involving businesses and organizations dedicated to accelerating the development and implementation of open, disaggregated, and standards-based technology and network infrastructure solutions within the telecommunications sector. The organization has over 500 members, and its work has resulted in the development of a number of open standards and specifications. The TIP's projects have also been adopted by a number of major operators around the world. The TIP's work outlines end products that meet specific commercial use cases that operators need. The TIP organizes multiple project groups (PGs) that concentrate on products, solutions, and software across various network domains, including RAN, TN, and CN, as well as various management layers.

Within the various PGs, the OpenRAN is an initiative for enabling an open ecosystem for building the 3GPP-defined NG-RAN architecture based on the principles of open components and interfaces for existing 4G, 5G, and beyond mobile networks. The primary goal of OpenRAN PG within the TIP is to develop end products and solutions, foster vendor diversity for network service providers, and introduce innovative platforms for network management. The group collaborates with operators, vendors, system integrators, and global stakeholders to align requirements for different components of OpenRAN networks, including O-RUs, O-DUs, and O-CUs. OpenRAN PG concentrates on building, testing, and validating Open RAN products at scale [75]. The solutions developed undergo thorough testing and validation in laboratory environments through TIP Community Labs and PlugFest.

The OpenRAN PG is organized into the following two main work streams [76]:

- **Component Subgroups**: These subgroups are dedicated to enhancing the performance of individual OpenRAN components, encompassing software and hardware such as RU, DU, CU, radio intelligence automation (RIA), and OpenRAN orchestration and management automation (ROMA).
- **Segment Subgroups**: These subgroups are concentrating on integrated RAN solutions tailored for specific network use cases to enhance deployment scenarios, both outdoor and indoor.

The OpenRAN PG released a technical priorities document, Release 3, in April 2023, presenting their prioritized requirements for Open RAN. This document comprehensively covers main scenarios, radio configurations, and hardware and software requirements for each building block within the Open

RAN framework of the TIP. The primary focus of Release 3 is to advance requirements related to SMO and RIC, with significant enhancements in underlying cloud infrastructure, O-CU, O-DU, and O-RU.

Notably, this release places a heightened emphasis on security considerations and challenges, consolidating security requirements in a dedicated section. It also explores energy efficiency topics in more detail, identifying new requirements across various streams. The goal is to accelerate the development of competitive Open RAN solutions in Europe and globally, promoting widespread technology adoption [76]–[78].

4) *Small Cell Forum*: The small cell forum (SCF) is a global organization focused on developing technical and commercial tools to accelerate the adoption of flexible, cost-effective, and scalable cellular network infrastructure. Throughout its existence, SCF has played a key role in standardizing essential elements of mobile network technology, including functional API (FAPI), network FAPI (nFAPI), and the enhancement of the X2 interface. These specifications enable an open, multi-vendor platform, thereby reducing the barriers to the densification of stakeholders in the wireless communication industry [79].

The SCF has established its own Open RAN ecosystem with a particular emphasis on small cells. The introduction of the nFAPI protocol by SCF marks the pioneering of split option 6 [59], which divides the MAC layer and physical layer (PHY), housing the PHY in the small cell RU (S-RU). The SCF nFAPI is pivotal in empowering the Open RAN ecosystem by facilitating interoperability, allowing a small cell CU/DU to connect seamlessly with an S-RU [80].

The SCF promotes openness and interoperability in small cell networks in order to allow diverse architectures while maintaining a common platform. To simplify integration, SCF provides tools, deployment blueprints, and support for testing, including the SCF disaggregated RAN transport study (DARTs) [81]. Emphasizing open testing and certification is crucial to instilling confidence among operators and facilitating the widespread adoption of Open RAN. SCF, O-RAN Alliance, and TIP have dedicated considerable efforts to support standardized testing processes across the industry, including actively participating in plugfests [79].

The SCF collaborates with O-RAN Alliance, 3GPP, OpenAirInterface (OAI), and many other organizations across technical, commercial, and regulatory eras. SCF aims to drive Open RAN adoption in all domains, resulting in significant growth in the deployment of virtualized open RAN. The combination of open systems, open-source code, and shared spectrum has the potential to empower numerous new deployers, particularly in crucial areas like enterprise and smart city environments where small cells are indispensable [79], [81].

D. O-RAN-Related Open Source Projects

The software community is dedicated to seamlessly aligning software reference implementations with the O-RAN architecture and specifications. In this context, the OSC assumes various responsibilities, including the development of open-source software, collaboration with other open-source commu-

TABLE II
SUMMARY OF CONTRIBUTIONS AND FOCUS AREAS ACROSS MULTIPLE WGS SUPERVISED BY THE TSC WITHIN THE O-RAN ALLIANCE.

Group	Title	Principal Areas of Focus and Notable Contributions
WG1	Use Cases and Overall Architecture WG	<ul style="list-style-type: none"> • Exploring and defining use cases, system-level requirements, deployment scenarios, and a comprehensive architecture for O-RAN • Investigation into network slicing within O-RAN, including defining use cases, requirements, and introducing slicing-aware architecture with interface extensions • Coordination of proof of concepts to demonstrate O-RAN products to the market
WG2	Non-RT RIC and A1 Interface WG	<ul style="list-style-type: none"> • Defining an architecture for Non-RT RIC, incorporating the R1 interface to connect the Non-RT RIC framework with Non-RT RIC applications (rApps) • Expanding R1 services within Non-RT RIC and integrating interfaces with the management components of the SMO Framework • Proposal and coverage of the A1 interface between the Non-RT RIC and the Near-RT RIC, including associated use cases and applications
WG3	Near-RT RIC and E2 Interface WG	<ul style="list-style-type: none"> • Specifying E2 interface between the Near-RT RIC and the E2 nodes • Defining the Near-RT RIC architecture and introducing application programming interfaces (APIs) for the Near-RT RIC platform and the Near-RT RIC applications (xApps) • Defining use cases, requirements, and management specifications for the Near-RT RIC, and contributing to service models for E2 interface and E2 nodes
WG4	Open Fronthaul Interfaces WG	<ul style="list-style-type: none"> • Establishing specifications for an open fronthaul (O-FH) interface between O-RAN DU (O-DU) and O-RAN RU (O-RU) • Setting standards for Control, User, Synchronization, and Management Plane protocols with corresponding YANG models for O-FH link • Developing specifications for transport interfaces and conducting O-FH interoperability tests
WG5	Open F1/W1/E1/X2/Xn Interface WG	<ul style="list-style-type: none"> • Providing interoperable multi-vendor specifications aligned with 3GPP standards for F1, W1, E1, X2, and Xn interfaces, enhancing O-RAN architecture • Defining specifications for O1 interface, covering O-RAN CU (O-CU) and O-DU, including operations and maintenance (OAM) functions • Developing open MH and backhaul (BH) interoperability test specifications
WG6	Cloudification and Orchestration WG	<ul style="list-style-type: none"> • Specifying cloud-native and virtualized infrastructure for hosting O-CU and O-DU, focusing on hardware-software decoupling • Providing technology and reference designs for leveraging commodity hardware platforms • Identifying use cases, deployment scenarios, and requirements for cloud resource hosting, and defining high-level orchestration architecture for SMO Framework and O-Cloud interaction
WG7	White-box Hardware WG	<ul style="list-style-type: none"> • Specifying standards for comprehensive reference design of high-performance, spectral efficient and energy efficient white box base stations • Promoting decoupled software and hardware platform for O-RAN components • Addressing outdoor and indoor cells with various split options, along with O-FH interface
WG8	Stack Reference Design WG	<ul style="list-style-type: none"> • Developing software architecture, design, and release plan for O-CU and O-DU, tailored for NR protocol stack • Providing specifications for interoperability testing of O-CU and O-DU deployment scenarios with other O-RAN components and interfaces
WG9	Open X-haul Transport WG	<ul style="list-style-type: none"> • Designing an open TN within O-RAN, meeting FH, MH, and BH service requirements • Concentrating on the open transport domain, including transport equipment, physical media, and associated control/management protocols within the TN
WG10	OAM for O-RAN	<ul style="list-style-type: none"> • Specifying OAM architecture for O-RAN and management services for O1 interface, including unified operation and notification mechanisms • Developing information models and data models for OAM architecture in O-RAN
WG11	Security WG	<ul style="list-style-type: none"> • Establishing specifications for O-RAN's security, including its NFs, interfaces, xApps, and rApps • Defining requirements, use cases, architectures, and protocols to ensure security and privacy of stakeholders within the O-RAN paradigm
SDFG	Standard Development Focus Group	<ul style="list-style-type: none"> • Leading in formulating standardization strategies for the O-RAN Alliance and serve as the primary interface to other relevant SDOs • Managing coordination of both incoming and outgoing liaison statements
IEFG	Industry Engagement Focus Group	<ul style="list-style-type: none"> • Engaging with leading industry players and members of the O-RAN Alliance to drive adoption, spread, and ongoing innovation of O-RAN-based technologies and solutions
OSFG	Open Source Focus Group	<ul style="list-style-type: none"> • Managing O-RAN Alliance's open-source activities, including establishing the O-RAN software community (OSC) and developing open-source related strategies • Collaborating with other open-source communities to drive innovation and adoption of O-RAN

Group	Title	Principal Areas of Focus and Notable Contributions
TIFG	Test & Integration Focus Group	<ul style="list-style-type: none"> Defining testing and integration approaches, coordinating specifications across WGs, including E2E test specifications and productization profiles Planning PlugFests and offering guidelines for third-party open testing and integration centers (OTICs), facilitating integration and verification processes
SuFG	Sustainability Focus Group	<ul style="list-style-type: none"> Focusing on enhancing energy efficiency and reducing environmental impact in O-RAN Collaborating with MVP-C to align initiatives across all WGs and FGs
nGRG	next Generation Research Group	<ul style="list-style-type: none"> Researching intelligent O-RAN principles for 6G and beyond standards Driving network evolution towards greater intelligence and performance through new technologies
MVP-C	Minimum Viable Plan – Committee	<ul style="list-style-type: none"> Providing roadmap for implementing comprehensive O-RAN solutions in commercial networks Managing definition of O-RAN features, including creation, prioritization, and tracking documents Approving feature creation and inclusion in relevant releases; collaborating and coordinating with all WGs and FGs
OSC	O-RAN Software Community	<ul style="list-style-type: none"> Leading the development of open-source software for O-RAN architecture in collaboration with the linux foundation (LF) Focusing on aligning with the open architecture and criteria of the O-RAN Alliance to deliver a solution suitable for commercial deployment

nities, and promotion of related projects and activities. As of this writing, multiple open-source platforms compliant with O-RAN are accessible for use by academics and research institutions, providing valuable tools for their work. In the following section, we will delve into some of the key contributors and participants in O-RAN implementations.

1) *ONAP*: The open network automation platform (ONAP) is an LF open-source project launched in 2017. It serves as a comprehensive platform designed for orchestrating, managing, and automating network and edge computing services. To address the needs of network operators, cloud providers, and enterprises, ONAP employs real-time and policy-driven orchestration and automation for both physical and virtual NFs. This capability facilitates swift automation of new services and the essential lifecycle management crucial for 5G and next-generation networks [75]. The project uses SDN and NFV technologies to automate 5G networks. ONAP contains complete management and orchestration (MANO) layer functionality that is consistent with the NFV architecture of ETSI. In addition to fault, configuration, accounting, performance, security (FCAPS) features, ONAP also contains a framework for designing network services [82].

There exist robust relationships and interdependencies between ONAP and OSC, deploying a SMO Framework and incorporating the Non-RT RIC functions [83]. The ONAP is collaborating with the OSC to enhance coordination, minimize redundant efforts, and streamline work. A compilation detailing shared areas of interest where ONAP and OSC intersect are available at [84]. The ongoing study of the use case, “ONAP/3GPP & O-RAN Alignment-Standards Defined Notifications over VES” serves to facilitate alignment between ONAP, 3GPP, and O-RAN. This contribution aims to empower ONAP to adhere to O-RAN Alliance and 3GPP standards, potentially encouraging participation from companies aligned with O-RAN Alliance and 3GPP [85].

The Kohn release of ONAP further focus on O-RAN integration, cloud-native NF orchestration improvements, and

intent-driven closed-loop autonomous networks [86]. ONAP includes modeling and orchestration functionality of a slice including 5G RAN, core, and transport network slice subnets. More specifically, ONAP includes workflows and user interfaces for the communication service management function (CSMF) and network slice management function (NSMF) with an interface to an external network slice subnet management function (NSSMF). This functionality allows the design, orchestration, and termination of an network slice [87].

2) *OpenAirInterface*: The OpenAirInterface software alliance (OSA) is a nonprofit organization founded by a French research institute, EURECOM, that supports a global community of researchers and industry contributors to the development of open-source software for the CN and RAN of 3GPP cellular networks. The Alliance supports the advancement of the 3GPP 5G cellular stack, which is included in the OAI software packages and deployed utilizing COTS hardware. The roadmap creation, quality assurance, and marketing of the OAI software packages used by the academic and business communities for various use-cases are all tasks that fall under the purview of the OSA. The goal of the OSA is to speed up OAI adoption.

In 5G, the OAI community and software assets are expanding at the quickest rate. Currently, OAI has the following projects: OAI 5G RAN, OAI 5G CORE, MOSAIC5G, and CI/CD. The newly created MOSAIC 5G (M5G) PG aims to transform RAN and CN into agile and open network-service delivery platforms. The primary emphasis of M5G PG is producing software implementations of the O-RAN E2 protocol, a flexible RIC called FlexRIC, a flexible Core controller namely FlexCN, an intelligent RAN and CN operator [88]. Northeastern University has also integrated OAI with the OSC RIC [89].

3) *Open Networking Foundation*: open networking foundation (ONF) is a consortium led by several network operators, playing a pivotal role in driving radical transformation within network infrastructure. The ONF’s software-

defined RAN (SD-RAN) project actively contributes open-source components to enhance Open RAN, by creating and testing O-RAN compliant network elements, fostering multi-vendor RAN solutions, and showcasing the potential of mixing components for innovation [90].

In close collaboration with the O-RAN Alliance and OSC, the primary goal of the platform is to develop open-source components for the O-CU CP, O-CU UP, and O-DU [40]. SD-RAN features a cloud-native uONOS-RIC (pronounced as micro-ONOS-RIC), a Near-RT RIC, an xApp development environment, and exemplary xApps for controlling Open RAN elements [91]. Deutsche Telekom has deployed a fully disaggregated 5G field trial, integrating components from more than 8 vendors using SD-RAN open-source uONOS-RIC. As the initial complete realization of the O-RAN architecture, encompassing O-RU, O-DU, O-DU, RIC, and xApps sourced from various providers, this marks a significant milestone in the advancement of the Open RAN movement. On January 9, 2024, ONF officially announced its merger with the LF. Subsequently, ONF's work is being introduced as distinct independent projects under the LF [91].

4) *srsRAN*: The srsRAN project, developed by software radio system (SRS), is an open-source RAN solution supporting both 4G and 5G technologies, featuring an ORAN-native gNB. This comprehensive RAN solution adheres to standards set by both the 3GPP and the O-RAN Alliance, covering the L1/L2/L3 protocol stack with minimal dependencies [92].

The srsRAN-based gNB offers flexibility for users to deploy a monolithic gNB on a single machine or distribute RAN functionalities across multiple machines and geographic locations. This flexibility enables easy integration with third-party RICs, PHY solutions, and other O-RAN compliant hardware and software applications and use cases.

The project follows the 3GPP 5G architecture, implementing functional splits between DU and CU, with further disaggregation into CU CP and CU UP. srsRAN supports third-party Near-RT RIC and xApp through the FlexRIC framework, with the ultimate goal of fully supporting the E2 interface [93].

5) *OpenRAN Gym*: OpenRAN Gym, spearheaded by Northeastern University, is a collaborative open-source initiative crafted to facilitate AI-driven and experimental research within the Open RAN ecosystem [35], [94]. The primary goal is to bring together researchers from academia and industry, creating a dynamic and cooperative environment to advance cutting-edge solutions and innovations for Open RAN through vibrant collaboration. OpenRAN Gym builds on frameworks for data collection and RAN control enabling E2E design and testing of data-driven xApps by providing an O-RAN compliant Near-RT RIC and E2 termination [35]. Users can conduct data collection campaigns, prototype, and evaluate solutions across a variety of wireless environments and deployments before transitioning them to production networks.

The OpenRAN Gym architecture provided in [94] consists of following key components:

- The publicly and remotely accessible experimental wireless platforms like Colosseum, Arena, and PAWR program platforms for data collection, prototyping, and testing solutions in diverse environments [94]–[97].

- A softwarized RAN utilizing open protocol stacks like srsRAN and OAI for cellular networks.
- A data collection and control framework, such as SCOPE, providing key performance indicators (KPIs) to extract key performance measurements (KPMs) from the RAN and dynamically control it at runtime.
- An O-RAN control architecture like CoIO-RAN, capable of connecting to the RAN through standardized interfaces like E2 termination, receiving runtime KPMs, and controlling it through AI/ML solutions like xApps/rApps.

E. Open Testbeds

In addition to the aforementioned open-source projects, several testbeds are available to aid in the implementation of softwarized 5G networks by leveraging certain open-source components. We elaborate on some of these testbeds below.

1) *Colosseum*: Colosseum is an open-access and publicly available extensive wireless testbed designed for experimental research, utilizing virtualized and softwarized waveforms and protocol stacks on a fully programmable "white-box" platform. Colosseum, with 256 state-of-the-art software-defined radios (SDRs) and a substantial channel emulator core, has the capability to simulate almost any scenario. This allows for the comprehensive design, development, and testing of solutions at scale across various deployments and channel conditions. It achieves high-fidelity reproduction of radio frequency scenarios through FPGA-based emulation employing finite-impulse response filters. These filters accurately model the taps of desired wireless channels, applying them to signals generated by the radio nodes to faithfully replicate real-world wireless environments [95], [97]. OpenRAN Gym has been intricately developed within Colosseum, facilitating experimentation with E2E O-RAN compliant networks, as well as enabling data collection and AI-driven model development, among other functionalities [35].

2) *POWDER*: Platform for Open Wireless Data-driven Experimental Research (POWDER) is a versatile infrastructure tailored to support a wide range of software-defined experiments. It is a city-scale wireless testbed, infrastructure spanning outdoor areas incorporating multiple SDRs, an indoor laboratory setup for over-the-air experiments, and a wired attenuator matrix [97]. The principal objective of POWDER is to foster experimental research in heterogeneous technologies, with a particular emphasis on areas such as 5G cellular technologies and network orchestration. POWDER is equipped with integrated features that streamline the setup of an O-RAN, facilitating quick implementation. Conducting experiments in POWDER involving the Near-RT RIC, xApps, the O-CU Subsystem, and open software for the SMO is a straightforward process [98], [99].

3) *COSMOS*: The Cloud enhanced Open Software defined MOBILE wireless testbed for city-Scale deployment (COSMOS) testbed is being deployed in West Harlem, New York City, as a component of the POWDER initiative. The COSMOS is focused on creating, developing, and implementing an advanced wireless testbed at a city-scale level. Its purpose is to facilitate real-world experimentation with next-generation

wireless technologies and applications. It has been certified by the O-RAN Alliance as an OTIC [97], [100].

The COSMOS architecture prioritizes ultra-high bandwidth and low-latency wireless communication, tightly integrated with edge cloud computing. Deployed in upper Manhattan, the COSMOS testbed comprises 40-50 advanced software-defined radio nodes, complemented by fiber-optic front-haul and back-haul networks, as well as edge and core cloud computing infrastructure. Through a web-based portal, researchers can remotely conduct experiments on the COSMOS testbed, accessing various facilities for experiment execution, measurements, and data collection [100].

4) *Arena*: Arena stands as an innovative open-access wireless testing platform, revolutionizing research in sub-6 GHz 5G and beyond spectrum exploration. Anchored by a grid of ceiling-mounted antennas within a spacious office environment, each antenna seamlessly interfaces with programmable SDRs. This amalgamation of 12 computational servers, 24 symbol-level synchronized SDRs, and a total of 64 antennas imbues Arena with unparalleled computational prowess and scalability, ideal for pioneering technology development within densely populated spectrum bands [96]. Operating on a meticulously crafted three-tier design, Arena strategically allocates servers and SDRs within a dedicated room, while antennas elegantly adorn the office ceiling, linked to radios via extensive 100 ft-long cables. This configuration guarantees a dynamic, scalable, and reproducible real-time experimental environment, faithfully replicating real-world wireless scenarios [96], [97].

5) *X5G*: X5G, a pioneering private 5G network testbed at Northeastern University, Boston, merges open-source and programmable components from PHY to CN. Notably, it stands as the first fully programmable multi-vendor and O-RAN compliant testbed, a collaborative endeavor involving Northeastern, NVIDIA, and OAI. Accelerated by NVIDIA graphics processing units (GPUs) at Layer 1 and built on OAI for layers 2 and 3, this integration leverages the SCF FAPI for seamless interaction between the MAC and PHY layers. Such integration enables the inline acceleration of demanding PHY tasks on the GPU, fostering scalability and facilitating AI/ML integration within the RAN. The NVIDIA aerial RAN CoLab (ARC) platform operates on a specialized multi-vendor infrastructure, featuring 8 servers for the CU and DU, along with 4 RUs suitable for lab installations. Additionally, it incorporates O-RAN 7.2x FH and timing hardware, as well as a dedicated 5G CN. NVIDIA ARC and OAI collaborate to provide enhanced performance while upholding the openness and accessibility characteristic of open-source systems, marking a significant stride forward in the realm of intelligent 5G and beyond use cases [101].

6) *5GENESIS*: The 5GENESIS initiative, backed by the European Union, aims to authenticate 5G KPIs across various applications, spanning controlled environments and large-scale events. It consolidates insights from multiple European Union projects and internal research and development efforts of its partners to establish a unified, E2E 5G infrastructure across five experimentation platforms in Europe. These platforms, while possessing unique capabilities, seamlessly interface and operate cohesively with one another within the 5GENESIS

facility, which serves as a versatile hub for validating KPIs, conducting additional demonstrations, and evaluating pivotal 5G and beyond use cases. The trials conducted within the facility focus on confirming essential 5G-PPP KPIs, thereby inherently assessing the capabilities and performance of each constituent platform [102].

III. IN-DEPTH ANALYSIS OF O-RAN ARCHITECTURE WITH A PARTICULAR EMPHASIS ON NETWORK SLICING

The O-RAN architecture is composed of various open interfaces, protocols, transport links, NFs, and management functions (MFs); collectively referred to as O-RAN components. The grand objective of such an open and programmable architecture is to decrease the need for proprietary hardware and software implementations and to create a multi-vendor and standard-compliant wireless network infrastructure [63]. By employing open interfaces and open-source software, the control plane is isolated from the user plane within the O-RAN architecture [44]. The openness also creates a modular base station software stack that is deployable on COTS hardware [37]. Through these groundbreaking innovations, the quintessential goals of the O-RAN Alliance namely, fostering openness, promoting vendor independence, and enhancing programmability are not just achievable but exquisitely realized [54], [103]. The openness of the O-RAN components expedites the provisioning of new services for end-users. The openness of the interfaces in O-RAN architecture brings service agility and cloud-scale economics to smaller vendors and network operators, allowing them to introduce new services or customize the network to meet their specific needs [61]. Open interfaces also enable multi-vendor deployments, making the supplier ecosystem more competitive and vibrant [104]–[106].

In addition to openness and vendor diversity, certain ML-based and AI-assisted features, components, and architectural solutions have been introduced by the O-RAN Alliance [104], [107]. The goal is to integrate intelligence and automation into the operations and maintenance of the O-RAN architecture [48], [108]. The integration of automation and intelligence can be achieved by the utilization of state-of-the-art ML-assisted algorithms, including supervised learning, unsupervised learning, deep learning, reinforcement learning, and many others [104]. These algorithms can be deployed both at the network layer and the management layer [108]. The deployment of these algorithms makes the operation and maintenance of O-RAN simpler, resulting in a reduction in OPEX [109]. Moreover, the automation and intelligitization of the O-RAN architecture can also reduce human intervention in the loop and increase the accuracy to handle the network complexity [110].

In this section, we will explore the latest O-RAN architecture in a detailed manner, with a special emphasis on the network slicing aspects. We will describe its components and interfaces that comprise the O-RAN architecture and further study the features designed for network slicing. Additionally, we will discuss MFs related to network slicing defined by the 3GPP, ETSI, and ONAP. Moreover, we will provide an insight into the underlying infrastructure, including the O-Cloud sites, open transport network, and open cellular sites.

A. Major Components of the O-RAN Architecture

The O-RAN architecture is founded on the disaggregation paradigm of a cellular base station, featuring multiple logical and physical units responsible for different components and interfaces within the radio network protocol stack. Figure 2 illustrates that the O-RAN architecture is composed of four major components: the O-RAN gNodeB (O-gNB), the RIC, the SMO Framework, and the underlying infrastructure. The O-gNB part includes the radio functionalities of an O-RAN slice. These functionalities perform tasks associated with modulation, coding, resource scheduling, and many others in both upstream and downstream directions. The O-gNB consists of the O-CU, O-DU, and O-RU. The RIC comes in two types: the Non-RT RIC and the Near-RT RIC, each designed to handle specific control loop and latency constraints [12]. The SMO Framework includes the Non-RT RIC, slice MFs, and other SMO functions [22]. The SMO Framework serves as an automation platform dedicated for the management and orchestration of O-RAN radio resources and RAN slices [111]. The underlying infrastructure is responsible for hosting the components of an O-RAN slice. It includes O-Cloud sites and transport links.

In the remaining parts of this section, we discuss each of the three major components in a detailed manner. We also explain how they contribute to the implementation of network slicing in the Release 3 O-RAN architecture.

B. O-gNB (E2 Nodes) and its Corresponding Interfaces

Figure 2 illustrates that each O-gNB is divided into several logical nodes within the O-RAN architecture. These nodes include the O-CU, the O-DU, and the O-RU, or a combined O-RAN eNB (O-eNB). They are collectively referred to as the E2 nodes in O-RAN Alliance terminology [112]. In the following, we provide their detailed overview, along with a detailed description of their respective open interfaces.

1) *O-RAN Centralized Unit*: The O-CU is a logical node that implements the higher layer protocols of the RAN stack, including the radio resource control (RRC) layer, which controls the life cycle of the connection; the service data adaptation protocol (SDAP) layer, which controls the QoS of traffic flows of bearers; and the packet data convergence protocol (PDCP), which, among other things, handles packet reordering, packet duplication, and encryption for the air interface [16], [113]. The O-CU terminates the E2 interface to the Near-RT RIC and the O1 interface towards the SMO Framework [22]. The O-CU includes one O-CU control plane (O-CU-CP) and possibly multiple O-CU user plane (O-CU-UP), which communicate with each other through the E1 interface [44], as shown in Figure 2.

According to the 3GPP specifications, the O-CU shall support functionalities associated with network slicing. The O-CU-UP may either be built as a single instance for each network slice or it can be shared across many slices depending on the individual requirements of each slice [16]. The O-RAN architecture extends network slicing functionalities and features beyond those defined by the 3GPP by leveraging the E2 interface and dynamic slice optimizations provided by the Near-RT RIC [114]. Moreover, the O1 interface supports more

configuration parameters related to network slicing in order to further enhance the capabilities of the O-RAN architecture. The O-CU is also expected to carry out slice-specific resource allocation and isolation measures using slice awareness capabilities. These nodes are first configured using the O1 interface according to the requirements of the individual slices, and they are subsequently modified for different slicing use-cases dynamically by the Near-RT RIC through the E2 interface. The O-CU may need to create and send certain performance metrics (PMs) across the O1 and E2 interfaces in response to requests for PMs from the SMO Framework and the Near-RT RIC. These PMs can be utilized for slice performance monitoring and slice SLA assurance [52], [115].

2) *O-RAN Distributed Unit*: The O-DU is a logical node that hosts the lower layer protocols of the RAN stack and serves as a baseband processing unit that handles the high PHY, MAC, and radio link control (RLC) layers [116]. The O-DU can be provided in the form of a virtualized network function (VNF) that can be hosted within a virtual machine or a container at the edge cloud [16]. It terminates the E2, F1, and O-FH interfaces. In addition, it terminates the RLC, MAC, and high-PHY functionalities of the radio interface towards the UE and the O1 interface towards the SMO Framework [22], [52]. The O-DU is meant to link with numerous O-RUs. It terminates the Open FH M-Plane interface towards the O-RU, allowing for hierarchical or hybrid O-RU administration within O-RAN.

The O-DU supports slice-specific resource allocation strategies in the O-RAN slicing-aware architecture. The MAC layer needs to allocate and isolate the relevant physical resource blocks (PRBs) to specific network slices according to the O1 configuration of a PRB allocation along with O-CU directives over the F1 interface and the dynamic guidance received from the Near-RT RIC through the E2 interface [117]. Similar to the O-CUs, the O-DUs must also generate and send specific PMs through the O1 and E2 interfaces according to the requests from the SMO Framework and the Near-RT RIC, respectively. These PM can be used for the purpose of network slice performance monitoring and slice SLA assurance [52].

3) *O-RAN Radio Unit*: The O-RU is a physical node that houses the low-PHY layer and radio frequency (RF) processing functionalities within an O-gNB, considering the lower layer functional split option [12]. The O-RU serves as the endpoint for both the O-FH interface and the low-PHY functionalities of the radio interface that connect to the UEs. It also terminates the O-FH M-Plane interface towards the O-DU and/or the SMO Framework based on the deployment options. A single O-RU is supposed to serve multiple network slice instances [118].

4) *O-eNB*: The O-RAN architecture also incorporates the ability to integrate long term evolution (LTE) base stations, referred to as O-eNB within the O-RAN Alliance terminology. The O-eNB can take the form of either an evolved NodeB (eNB) or a next generation eNB (ng-eNB). The corresponding interfaces and protocols must also be supported by the O-RAN architecture. To ensure O-RAN compatibility, it is essential to support both the E2 and O1 interfaces to the O-eNB [22].

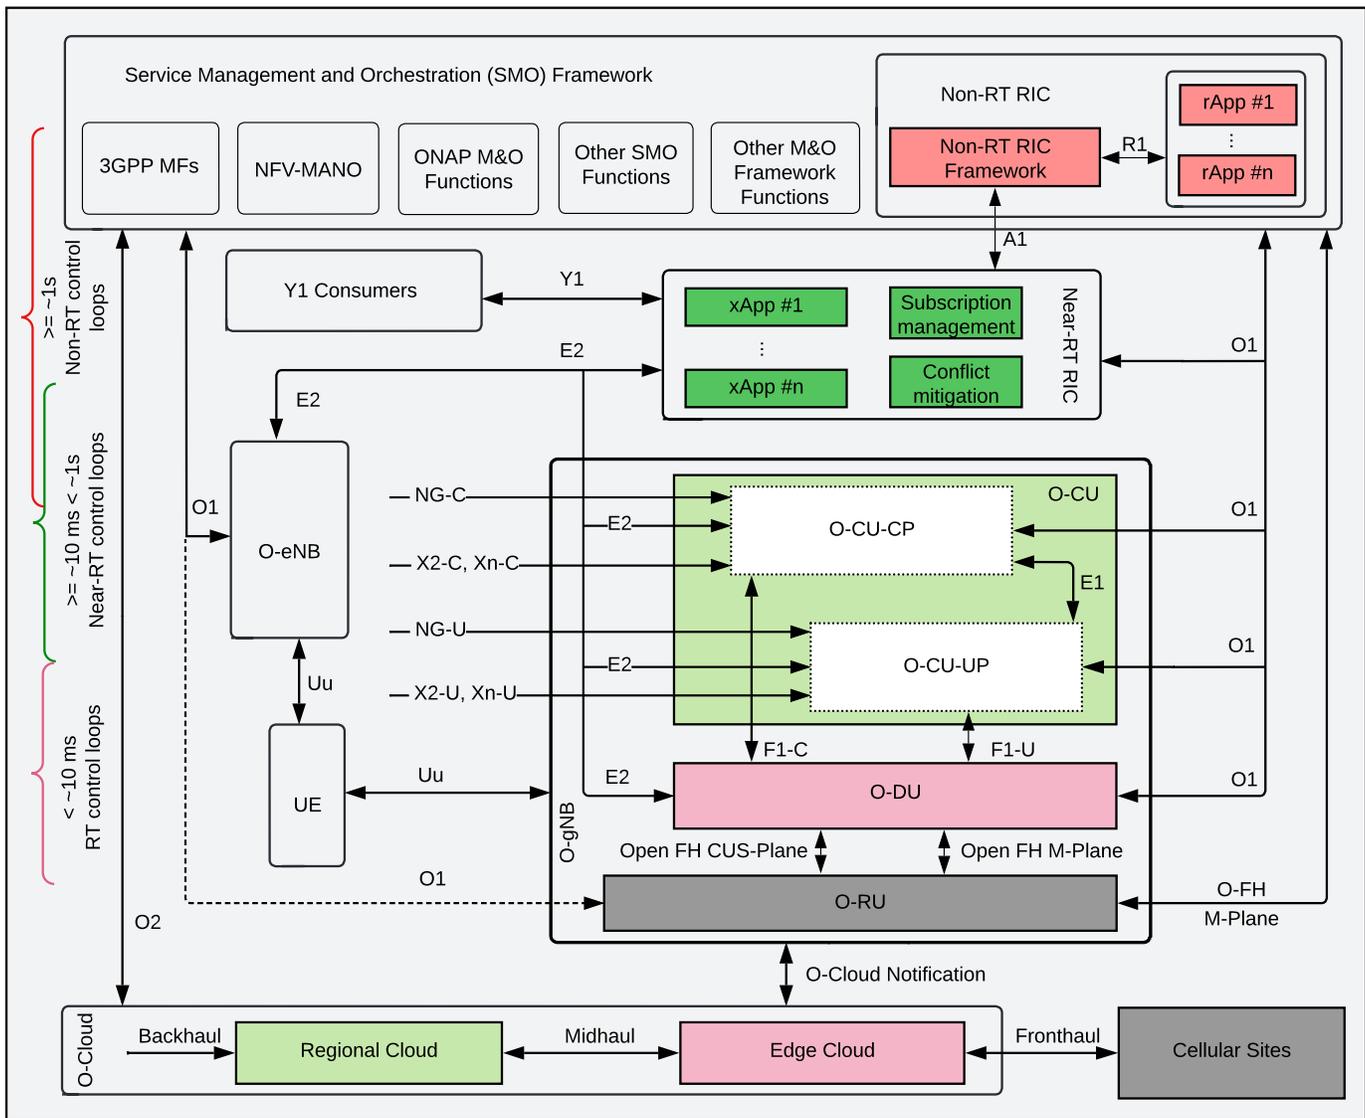

Fig. 2. O-RAN Release 3 Slicing-aware Reference Architecture

5) *E1 Interface*: The E1 interface acts as a control interface, linking the O-CU-CP and O-CU-UP entities within an O-gNB or O-eNB [119]. This interface is standardized by the 3GPP and plays a pivotal role in the O-RAN architecture, promoting efficient communication and operation. The utilization of standardized interfaces not only ensures the efficiency of the O-RAN architecture but also offers flexibility and scalability for future developments and advancements [120].

6) *F1 Interface*: The F1 interface is used to connect the O-CU and O-DU within an O-gNB [119]. The O-RAN employs the principles and protocol stack defined by the 3GPP for the F1 interface, as well as the formulation of interoperability profile specifications. Mirroring the O-CU's division into user plane and control plane, the F1 interface also comprises two distinct components: F1-C and F1-U [22].

a) *F1-C*: The F1-C interface handles control and signaling functions. It manages the exchange of control information between the O-CU-CP and the O-DU. Control plane functions typically involve activities such as setting up and releasing connections, managing handovers, and coordinating radio resource allocation.

b) *F1-U*: The F1-U interface is responsible for the actual user data transmission. It handles the transfer of user data between the O-CU-UP and the O-DU, playing a critical role in the efficient and reliable transport of user data between the O-RAN components.

7) *W1 Interface*: The W1 interface for the functional split of the eNB is specified in 3GPP Release 15. An ng-eNB comprises ng-eNB-CU and ng-eNB-DUs. These components, ng-eNB-CU and ng-eNB-DU, are linked through the W1 logical interface, which enables the separation of control plane and user plane functionalities with W1-C, and W1-U, respectively [121].

8) *X2 Interface*: The O-RAN has inherited the X2 interface from the 3GPP for the definition of interoperability profile specification and used to connect the O-CU with other eNBs in an E-UTRA NR dual connectivity (EN-DC) configuration. The X2-C and X2-U are two parts of the X2 interface for transmitting the control plane and user plane information, respectively [22].

9) *Xn Interface*: The O-RAN has adopted the principles and protocol stack of Xn interface, defined by 3GPP, for

the definition of interoperability profile specification. The Xn interface contains separate components Xn-C and Xn-U to connect the O-CU-CP and O-CU-UP, respectively, to other gNBs [22].

10) *NG Interface*: The NG interface is also an interface adopted by the O-RAN from the 3GPP to connect the O-CU and the 5G Core (5GC). The NG interface also has two components, NG-C and NG-U, for the control and user planes, respectively. The NG-C interface connects the O-CU-CP with the access and mobility management function (AMF), while the NG-U provides a link between the O-CU-UP and the user plane function (UPF) in the 5GC [22].

11) *Uu Interface*: The 3GPP designates the interface between the UE and the e/gNB as the Uu interface. The Uu interface encompasses a comprehensive protocol stack spanning from Layer 1 to Layer 3, constituting a complete entity that terminates within the NG-RAN architecture. When the NG-RAN is decomposed, various protocols conclude at distinct reference points, none of which has been explicitly defined by the O-RAN Alliance. Since the Uu messages still continue to travel from the UE to the targeted e/gNB managed function, the O-RAN architecture does not represent it as a distinct interface directed to a specific managed function [22].

12) *Y1 Interface*: The Near-RT RIC offers RAN analytics information services through the Y1 service interface to an authorized third party, called the Y1 consumer. These services are accessible to Y1 consumers upon mutual authentication and authorization. To access RAN analytics information, Y1 consumers within a public land mobile network (PLMN) trusted domain can subscribe to or request services via the Y1 service interface. Entities outside the PLMN trusted domain, acting as Y1 consumers, can securely utilize Y1 services through a standardized exposure function. Y1 consumers, unlike the other network elements as shown in Figure 2, are not denoted as logical O-RAN functions [22].

13) *Open Fronthaul Interface*: The O-RAN FH Specification outlines the splitting and virtualizing the conventional cell site, transforming it into an efficient system for the FH, MH, and BH with enhanced capacity, speed, and latency in the next-generation cellular networks. The physical layer is separated into high-PHY and low-PHY components, employing the functional split to outline the architecture of a disaggregated and virtualized gNB. The low-PHY resides in the O-RU while the high-PHY is hosted in O-DU [122]. The Open FH Interface establishes a connection between the O-DU and O-RU logical nodes, encompassing both the CUS-Plane and M-Plane [123], [124].

a) *C-Plane*: Control Plane specifically refers to the real-time control interactions between the O-DU and O-RU. C-Plane messages facilitate the exchange of data-associated control information necessary for processing user data, such as scheduling and beamforming commands, if such information is not supplied via M-Plane. These messages are transmitted for downlink and uplink commands independently. To enhance flexibility, C-Plane messages may be sent collectively or individually, depending on the relevant channel for conveying the information [124].

b) *U-Plane*: User Plane pertains to the transfer of in-phase and quadrature (IQ) sample data between O-DU and O-RU. To ensure coordination of C-Plane and U-Plane timing, the FH interface specifies that C-Plane messages must reach the O-RU ahead of the latest possible time for the first corresponding U-Plane messages. U-Plane messages will be encapsulated using a two-layered header approach, where the first layer includes an evolved CPRI (eCPRI) or IEEE 1914.3 common header indicating the message type, and the second layer is an application layer containing essential fields for control and synchronization [122], [124].

c) *S-Plane*: Synchronization Plane is concerned with the communication between the O-RU or O-DU and a synchronization controller, typically an IEEE 1588 Grand Master, that may be integrated into the O-DU. O-RAN encompasses the synchronization of frequency, phase, and time across all network elements O-DUs, intermediate switches, and O-RUs for both time division duplexing (TDD) and frequency division duplexing (FDD) features [124].

d) *M-Plane*: Management Plane refers to non-real-time management operations between the O-DU and the O-RU. Different modes of network connectivity between the O-RU and the O-DU, as well as the SMO Framework, are possible based on the transport topology. The fundamental requirement for the M-Plane is to establish E2E connectivity between the O-RU and the entities responsible for its management, including the O-DU, SMO Framework, or entities referred to as the O-RU Controllers.

The Open FH M-Plane employs a NETCONF/YANG-based system to manage various features such as installation, software, configuration, performance, fault, and file management for the O-RU. Two architectural models are supported for this: First, the hierarchical model, where one or more O-DUs manage the O-RU via a NETCONF-based interface. Second, the hybrid model, which allows direct logical interfaces between the management systems, such as the SMO Framework and the O-RU, in addition to the logical interface between the O-DU and the O-RU. For Multi-Operator O-RU, various architecture models involving different Shared Resource Operators are supported. In the hybrid model, the O-RU establishes E2E connectivity with the SMO, either through the O-DU or with direct logical communication. Importantly, there is no explicit signaling indicating hierarchical or hybrid configuration, and all NETCONF servers supporting the M-Plane specification must handle multiple sessions, with all the O-RUs capable of supporting both hierarchical and hybrid deployment [123].

C. RAN Intelligent Controller

The RAN intelligent controller (RIC) stands out as a significant advancement within the O-RAN architecture [125]. It epitomizes a software-defined NF to handle aspects of the eNB or gNB functionality, such as mobility management, traditionally confined to the base stations. By offering real-time visibility and control over O-RAN resources, the RIC plays pivotal role in the O-RAN disaggregation strategy, introducing essential features like multivendor interoperability, intelligence, agility, and programmability, thereby reshaping

the O-RAN landscape [125], [126]. Its integration into the O-RAN architecture empowers network operators to manage and optimize O-RAN resources in a flexible and intelligent manner [127], which is also very essential to realize the network slicing.

In addition, it configures network slices, orchestrates network operations, checks network performance, and instantly optimizes the RAN resources in real time by utilizing the open interfaces [126], [128]. As depicted in Figure 2, the RIC manifests in two distinct forms, each meticulously designed to cater to specific control loop dynamics and latency requirements. These two variants, namely the Non-RT RIC and the Near-RT RIC, play critical roles within the O-RAN architecture [122]. In the subsequent sections, an exhaustive exploration of both types of RIC will be provided, elucidating their functionalities, applications, and significance within the broader context of network optimization and management.

1) *Near-Real-Time RAN Intelligent Controller*: The Near-RT RIC serves as a logical entity, facilitating precise and close-to-real-time control and optimization of the E2 nodes and resources. The Near-RT RIC resides close to the O-gNB and interacts with them to optimize its functionalities [129]. It achieves this through meticulous data collection and actions performed via the E2 interface [127]. Operating seamlessly within a near-real-time control loop, the Near-RT RIC adheres to a time span ranging from 10 milliseconds to 1 second [130]. It functions as a software framework tailored for hosting xApps, which are intelligent, autonomous, and microservice-based applications [131].

During onboarding, these xApps can identify the data they collect, process, consume, and provide [22]. The Near-RT RIC assumes the responsibility of managing and optimizing O-RAN resources in near-real-time to meet the dynamic and diverse requirements of various applications and services [17]. This optimization is achieved by integrating xApps, deployable to the Near-RT RIC as needed, to offer specific functionalities such as radio resource management (RRM) [60], [131]. These xApps leverage UE and cell-specific metrics collected through the E2 interface to optimize O-RAN resources and functionalities in real time, ensuring efficient utilization of network resources and an enhanced user experience [112], [132].

Furthermore, the Near-RT RIC gains direct control over the E2 nodes and their resources through policies and information transmitted via the A1 interface from the Non-RT RIC [130], [133]. In specific scenarios, the Near-RT RIC has the authority to monitor, suspend, stop, override, or control an E2 node based and its resources on rules associated with a function exposed in the E2 service model [22], [134].

The Near-RT RIC plays a crucial role in facilitating network slicing within the O-RAN architecture. Specifically, it empowers near-real-time optimization of O-RAN slice subnets through the utilization of xApps. This optimization involves communication with O-CU and O-DU via the E2 interface. To ensure efficient operation, xApps must possess awareness of O-RAN slices, allowing them to employ slice-aware algorithms for the assurance of network slice SLA [52]. In response to this challenge, a growing body of research has emerged proposing xApps for various optimization problems

within the O-RAN architecture. Several notable examples can be found in [132], [108], and [135], where authors present an array of xApps tailored to specific applications.

The xApps leverage AI/ML models guided by A1 policies and generated by the Non-RT RIC [26], [57]. These policies serve as a foundation for intelligent decision-making within the network. When O-RAN slices are operational, slice-specific PMs are gathered from the E2 nodes and subsequently transmitted to the Near-RT RIC. The Near-RT RIC integrates this information with slice configuration data, facilitating dynamic optimization of the slices. This collaborative approach between the Non-RT RIC and Near-RT RIC associated with AI/ML is aimed at enhancing the overall efficiency of network slicing within the O-RAN architecture [5], [130].

2) *Non-Real-Time RAN Intelligent Controller*: The Non-RT RIC stands as a core component of the O-RAN architecture. It is responsible for non-real-time management and optimization of the O-RAN components and resources [112]. As illustrated in Figure 2, the Non-RT RIC also facilitates the execution of third-party applications known as rApps. These modular software applications are designed to use the capabilities offered by the Non-RT RIC Framework's R1 interface to provide additional value services related to O-RAN operation [54]. Examples include driving the A1 interface and suggesting values and actions for potential implementation via the O1 and the O2 interfaces [22].

The Non-RT RIC autonomously configures all O-RAN components, eliminating the need for network operator intervention. The MNOs can leverage the Non-RT RIC to gain insights into network operations and optimize them in real-time [129]. Its functionality is intrinsic to the SMO Framework within the O-RAN architecture and offers an A1 interface to the Near-RT RIC. The Non-RT RIC can employ data analytics and AI/ML model training to develop RAN optimization actions, leveraging SMO services like data gathering and provisioning services provided by O-RAN nodes [136]. The Non-RT RIC distributes trained models to the Near-RT RIC for runtime execution. The Non-RT RIC is responsible for applying the AI/ML algorithms to deliver innovative use-cases within the O-RAN architecture [137]. Therefore, the Non-RT RIC is a key component in O-RAN, delivering highly complex functionalities related to the O-RAN slicing.

The Non-RT RIC retrieves slice-specific PM and configuration parameters, along with optional internal information, from the servers. The learning capabilities of AI/ML models can tackle complex problems, such as applying RRM policies [112]. Training models enable non-real-time optimization of slice-specific parameters over the O1 interface. The collected information and performance metrics are sent to the Near-RT RIC. The Near-RT RIC can use this PM, configuration, and other data for dynamic slice optimization to prevent potential SLA violations between network slices [31]. Furthermore, the Near-RT RIC controls the network resources through the E2 interface, and the Non-RT RIC controls the cloud resources through the O2 interface based on decision made by the collected information [138].

3) *R1 Interface*: The R1 interface resides within the internal structure of the Non-RT RIC. Through this interface,

the Non-RT RIC framework provides services that empower rApps to access data for initiating intelligent policy decisions and optimizing O-RAN operations. Additionally, rApps utilize the R1 interface to exchange authorized enrichment data with the Near-RT RIC and to share services and analytics within the Non-RT RIC framework [138], [139].

4) *A1 Interface*: The A1 interface, defined by the O-RAN Alliance, serves to link the Near-RT RIC with the Non-RT RIC. Through the A1 interface, the Non-RT RIC can provide policy guidance to the Near-RT RIC, referred to as A1 policies [45]. The Near-RT RIC components communicate with the A1 policy functions implemented over the A1 interface. These A1 policy functions utilize the A1 interface to facilitate the provisioning of policies for specific UE or groups of UEs, monitor policy states, provide basic feedback from the Near-RT RIC, offer enrichment information as required by the RICs, and streamline the training, distribution, and inference of ML models [45], [140]. Slicing use-cases, such as slice SLA assurance, can utilize these services. For example, the Non-RT RIC can employ policy management via the A1 interface to transmit slice-specific policies, guiding the Near-RT RIC in slice resource allocations and slice-specific control activities, while also receiving slice-specific policy feedback [52].

5) *E2 Interface*: The E2 interface serves as the connection point between the Near-RT RIC and E2 nodes, offering support for E2 primitives such as Report, Insert, Control, and Policy. These primitives empower both RICs to manage the services provided by the E2 nodes, enabling control over procedures and functionalities. Specifically, the Near-RT RIC, with a focus on xApps, manages specific operations within E2 nodes, necessitating the deployment of an E2 agent at the node [130].

E2 nodes communicate information to the Near-RT RIC via the E2 interface, notifying it about functions that xApps may handle [31], [133]. Furthermore, the E2 node's interface facilitates the collection of measurements from the O-RAN to the Near-RT RIC, either periodically or in response to predetermined trigger events. This interface connects one or more cells, slices, QoS classes, or specific UEs to both control and data collection operations [141].

Slice-specific xApps utilize these primitives to influence the configurations and behaviors of E2 nodes related to slices. Examples include RRM, radio resource allocations, MAC scheduling policies, and other configuration parameters embedded in various O-RAN protocol stacks. The RIC employs the E2 interface for configuring and receiving slice-specific reports and performance data from the E2 nodes [52], [136].

D. The SMO Framework and its Corresponding Interfaces

In alignment with the primary objectives of the O-RAN Alliance, the 5G RAN architecture is expected to be highly flexible, reliable, scalable, and interoperable across multiple vendors for diverse deployment scenarios. It operates on COTS white box hardware in a cloud-native and virtualized infrastructure, leveraging automation mechanisms as well as AI and ML algorithms [104]. Therefore, the automation and intelligentization of the management and orchestration of the O-RAN architecture take up the utmost significance [142]. The autonomous management and orchestration of the O-RAN

components are executed by the SMO Framework. The SMO Framework is a set of integrated MFs and services presented within the O-RAN architecture [48], as shown in Figure 2. It encompasses the management systems and functions of various SDOs. The SMO Framework utilizes standardized service-based management interfaces to enable interoperability among the MFs of various SDOs within the SMO Framework [48]. Operating on the principle of services based architecture (SBA), the SMO Framework facilitates the provision and consumption of services such as authentication, authorization, service registration and discovery, data management, and trained model sharing, among others [22].

The SMO Framework manages the FCAPS operations for O-RAN components via the O1 interface. It enables intelligent optimization and RRM via the Non-RT RIC, administers O-Cloud functionalities via the O2 interface, and provides platform resources and workload management. To execute functionalities associated with FCAPS, particularly from the SMO Framework to O-RU, an Open FH M-Plane interface is employed. The interface linking the Non-RT RIC and Near-RT RIC is denoted as the A1 interface. The Non-RT RIC acquires data from various components of O-RAN, develops or selects ML models, and transmits them to the Near-RT RIC via the A1 interface. The A1 interface is capable of supporting three service types: policy management, information enhancement, and ML model management [10], [52], [143].

The design of the SMO Framework, particularly the Non-RT RIC, allows for flexibility in implementation. This signifies that operators will have the ability to select which features to include or exclude in a Non-RT RIC implementation. The SMO Framework can also be connected to an E2E multi-domain service orchestrator, which connects domain-specific modules used by the SMO Framework to coordinate the network slices in each subnet (e.g., RAN, TN, and CN). This E2E Framework enables the on-demand creation and E2E management of network slices across a distributed 5G infrastructure. The SMO Framework can include and shall also meet the architectural requirements of the 3GPP, ETSI, and ONAP for network slicing using a set of MFs based on their respective specifications.

The MFs of these SDOs within the SMO Framework perform tasks such as creating, operating, modifying, and terminating a network slice, as well as scaling the underlying resources. The O-RAN Alliance preserves the network slicing concepts, procedures, and functionality of architectural components defined by the 3GPP, ETSI, and other related SDOs. The O-RAN architecture keeps consistency with 3GPP in terms of the architectural design and positioning of network functions to the most possible extent but defines some general principles on top of the network slicing principles of the aforementioned SDOs. For instance, interface specifications shall be compatible with 3GPP, standardized management service interfaces for O-RAN slicing management services shall be provided, multi-vendor interoperability shall be given, various network operator deployment options shall be supported, as well as management of slice subnets in multi-operator scenarios shall be provisioned.

1) *O1 Interface*: The O-RAN managed elements and the management entities within the SMO Framework are logically connected through the O1 interface, as shown in Figure 2. The goal of utilizing the O1 interface is to guarantee the operation and management of the O-RAN components, including FCAPS, software management, and file management, among many others. The O-CU, O-DU, and Near-RT RIC are among the major components managed by the O1 interface and enable the SMO Framework to access O-RAN NFs [144].

In O-RAN slicing, the O1 interface may be used for the configuration of O-RAN nodes with slice-specific parameters according to the service requirements of a network slice. The 3GPP has defined a slice-specific information model that includes RRM policy attributes to provide the ratio of PRBs among slices [34]. These models can be extended with additional information models to capture slice profiles and slice-specific configuration parameters to support the O-RAN slicing use-cases that also carry over the O1 interface. The interface may be further used for the collection of slice-specific performance metrics and faults from the O-RAN nodes [52].

2) *O2 Interface*: The O2 interface serves as an open logical interface that enables secure communication between the SMO Framework and O-Cloud sites, as introduced in [145]. It enables the life cycle management of VNFs that operate on O-Cloud infrastructure. The O-RAN functionalities within the network are hosted by the O-Cloud infrastructure, utilizing the O2 interface in SMO Framework to facilitate cloud infrastructure management and deployment processes. The O2 interface supports the orchestration of O-Cloud infrastructure resource management, such as inventory, monitoring, provisioning, software management, and life cycle management. It also facilitates the deployment of O-RAN NFs, offering logical services for controlling the deployment life cycle that make use of cloud resources. While the Non-RT RIC may be instantiated with other SMO functions as part of the SMO Framework, the O2 interface is not expected to be utilized for the life cycle management of the Non-RT RIC. The O2 interface is designed to be expandable, so new data or features can be introduced without necessarily altering the protocol or the processes. This interface supports a multi-vendor environment and is unaffected by particular SMO Framework and O-Cloud implementations. By rearranging network components, updating the system, or upgrading the system, operators who are linked to the O-Cloud may then manage and run the network using the O1 or/and O2 interfaces [146].

3) *3GPP Network Slicing MFs within the SMO Framework*: The 3GPP-defined MFs for the management and orchestration of network slicing are the CSMF, NSMF, NSSMF, and network function management function (NFMF). These MFs can be employed within the SMO Framework, considering the requirements defined by the 3GPP for network slicing. Furthermore, several functional and non-functional requirements for network slicing architecture have also been defined by the O-RAN Alliance in [52]. Both sets of requirements defined by the 3GPP and O-RAN Alliance are critical for the realization of network slicing in O-RAN architecture and the functionalities of the 3GPP MFs. The provision of management service (MnS) for a mobile network, which encompasses network

slicing, can be achieved through a collection of functional blocks as illustrated in Figure 3.

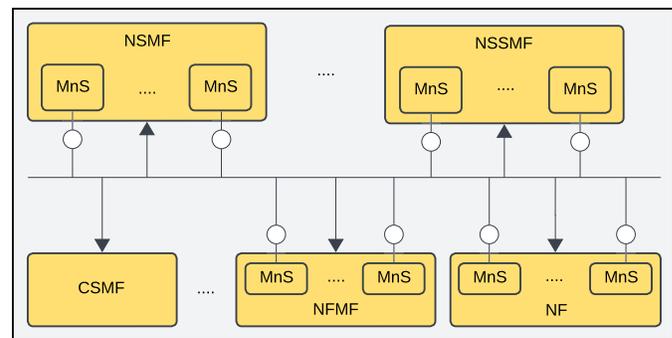

Fig. 3. 3GPP Management Architecture within the SMO Framework

In the following, we elaborate on the previously mentioned 3GPP MFs and their role in the realization of management and orchestration of O-RAN slices.

- **Communication service management function (CSMF)**: This MF translates the communication service requirements received from third parties – such as operations support system (OSS)/business support system (BSS), network slice as a service (NSaaS) tenants, and others – into network slicing requirements [147].
- **Network slice management function (NSMF)**: The NSMF is in charge of managing an E2E network slice after the CSMF determined its required requirements. It manages the resources required for hosting the communication services and interacts with the NSSMFs responsible for managing the Network Slice Subnet in that domain [147], [148].
- **Network slice subnet management function (NSSMF)**: The NSSMF in each network domain (i.e., RAN, transport, and core) instantiates the required resources based on the instructions of the NSMF. Each NSSMF orchestrates the domain-specific resources on its subnet to meet the service requirements in that subnet. For example, the RAN NSSMF is responsible for orchestrating the RAN portion of a network slice, such as life-cycle management, configuration management, performance management, and fault management of RAN slice subnets. Furthermore, the RAN NSSMF interfaces with the RIC for control plane operations related to O-RAN slices within the O-RAN architecture [147], [148].
- **Network function management function (NFMF)**: The NFMF offers NF management services within the NF management model. It manages multiple NFs and handle the application-level management of both VNF and physical network function (PNF) [48]. Additionally, it produces the NF provisioning service, which includes configuration management, Fault management, and performance management. At the same time, the NFMF consumes the NF provisioning service provided by VNFs and PNFs [148].

To provide seamless management and orchestration solutions, the SMO Framework can be customized to incorporate either all or some of the 3GPP-defined MFs mentioned earlier. The decision regarding the inclusion of these MFs pertains to

deployment considerations, which we discuss in Section IV.

4) *NFV-MANO within the SMO Framework*: The network functions virtualization management and orchestration (NFV-MANO) Framework is specified by the ETSI industry specification group (ISG) on NFV. The SMO Framework can also include the NFV-MANO [27]. Within the context of the SMO Framework, the NFV-MANO is responsible for the management and orchestration of the VNFs and virtual resources of an O-RAN slice. The NFV-MANO originally consisted of three functional blocks: the network function virtualization orchestrator (NFVO), the virtual network functions manager (VNFM), and the virtualized infrastructure manager (VIM). It also included an element management (EM). In Release 4, the ETSI ISG NFV added five new MFs in order to manage the containerized and transport aspects within the NFV-MANO Framework [149], [150]. Figure 4 illustrates all these functional blocks as well as the newly added MFs.

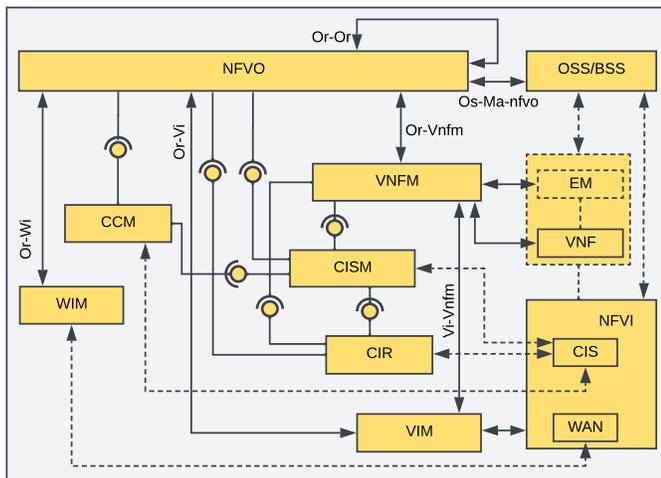

Fig. 4. NFV-MANO Architecture within the SMO Framework

In the following, we discuss these MFs and functional blocks (FBs), as well as the application within the SMO Framework, in a detailed manner.

- **Network function virtualization orchestrator (NFVO)**: The NFVO has two primary responsibilities: Firstly, it orchestrates NFV infrastructure (NFVI) resources across multiple VIMs fulfilling resource orchestration functions. Secondly, it manages the lifecycle of network services by performing network service orchestration functions, which include coordinating groups of VNF instances to collectively achieve a more complex function. The NFVO facilitates joint instantiation and configuration of these instances, establishes required connections between different VNFs, and manages dynamic configuration changes, such as scaling the capacity of the network service. The network service orchestration function relies on services provided by both the VNFM function and the resource orchestration function. The NFVO uses resource orchestration functionality to offer services that allow abstracted access to the NFVI resources independently of specific VIMs. Additionally, it governs VNF instances sharing resources within the underlying NFVI [148], [149].
- **Virtual network functions manager (VNFM)**: The VNFM is responsible for the lifecycle management of

one or more VNF instances within an network slice [150]. The VNFs can be of the same type or different types. The VNFM is also responsible for the FCAPS of the VNFs, and scaling up and down the VNFs in its service region [149].

- **NFV infrastructure (NFVI)**: The NFV considers software or hardware accelerators as supplementary resources capable of virtualization, which can be exposed as virtual accelerators within the VNF layer [151]. The NFVI includes all the underlying components of the infrastructure, comprising both the hardware and software necessary for hosting VNFs. It presents infrastructure resources in a virtualized form for utilization by VNFs and network services, encompassing virtual compute, virtual storage, and virtual network resources [149]. Nevertheless, it is essential to note that existing NFV-MANO specifications do not comprehensively address NFVI management aspects, especially concerning the management of physical infrastructure within the cellular network. As a result, complete support for full infrastructure management service (IMS) functionality is not achievable under the current specifications [151].
- **Virtualized infrastructure manager (VIM)**: The VIM is tasked with controlling and managing the computing, storage, and network resources of the NFVI within the underlying telecommunication infrastructure [150]. It is important to note that the actual deployment and maintenance of the VIM falls outside the scope of NFV-MANO. Nevertheless, the interfaces provided by VIM are within the scope [149]. Hence, the NFV-MANO utilizes this interface to influence the decisions made regarding the three types of resources within the underlying infrastructure layer.
- **Element management (EM)**: The EM, which is equivalent to the NFMF within the 3GPP management system, manages the FCAPS of a VNF from a functional and application points of view. It is worth noting that the VNFM also manages the FCAPS of a VNF, but exclusively from a virtualization perspective [149].
- **Container infrastructure service (CIS)**: In the container-based NFV-MANO, the CIS is the execution environment for a container cluster where the container-based services run [149]. As ETSI NFV Release 4 promotes enhanced functionalities, CIS is becoming increasingly crucial for efficient and agile containerized network deployments.
- **CIS management (CISM)**: The CISM is responsible for the management and orchestration of CIS instances and CIS archival within the NFV-MANO. It interacts with other NFV-MANO components like the VNFM and Orchestrator, providing an abstraction layer for CIS functionalities. Its capabilities encompass container network, workload, compute, and storage management, along with container configuration executed by CIS [149].
- **CIS cluster management (CCM)**: The CCM function is responsible for handling the lifecycle and operation, as well as configuration, performance, fault, and resource management, of the CIS cluster within the NFV-MANO

[149]. It acts as the bridge between the orchestrator (overall NFV service provisioning) and the underlying CIS instances within the cluster.

- **Container image registry (CIR):** The CIR is responsible for container image management [149]. It is an internal repository used by the NFV-MANO to store and manage container images specific to their containerized network functions (CNFs) deployments. The CIR is also responsible for implementing security measures to control access and ensure image integrity, version control and lifecycle management of container images, and integration with continuous integration (CI)/continuous deployment (CD) pipelines for building and pushing new images.
- **WAN infrastructure manager (WIM):** The WIM provides management and orchestration services for multi-site connectivity service (MSCS). It establishes connectivity between the NFVI-point-of-presences (PoPs) using MSCS which abstracts the details of the connections on the transport network [149]. The NFVI-PoP is an ETSI's terminology, which is a synonym for O-Cloud O-RAN.

5) *ONAP Architecture within the SMO Framework:* ONAP provides a comprehensive platform to network operators, cloud service providers, and businesses for the orchestration, management, and automation of network and edge computing services and resources. Faster automation of new services and full lifecycle management, which are essential for 5G and beyond, are made possible by real-time, policy-driven orchestration and automation of PNFs and VNFs [152]. Figure 5 illustrates a simplified ONAP architecture from a functional perspective. The ONAP design time environment facilitates the onboarding of services and resources into ONAP, along with the design of necessary services. On the other hand, the ONAP runtime environment operates as a model- and policy-driven orchestration and control framework, automating the instantiation and configuration of services and resources.

The components of the ONAP architectural framework are briefly discussed in the following.

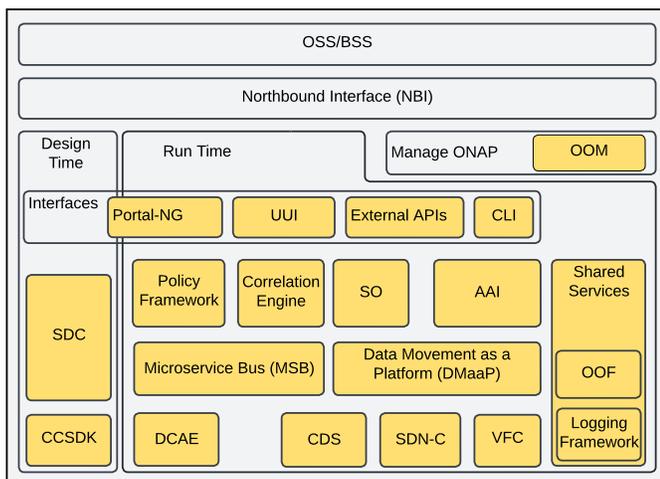

Fig. 5. ONAP Architecture: Microservices Interaction Diagram

- **ONAP operations manager (OOM):** The OOM is responsible for the complete life cycle management and orchestration of ONAP components. Furthermore, OOM contributes to the advancement of ONAP maturity by

introducing scalability and resiliency enhancements to the components under its management.

- **Use case user interface (UI):** The UI operations facilitate a broader spectrum of lifecycle management actions using a simple point-and-click interface, enabling operators to execute tasks more easily [153].
- **Service orchestrator (SO):** The SO automates sequences of activities, tasks, rules, and policies to execute specified processes required for the on-demand creation, modification, or removal of network, application, or infrastructure services and resources. Operating at a high level, the SO offers orchestration with a comprehensive view of the infrastructure, network, and applications [87].
- **ONAP optimization framework (OOF):** The OOF offers a declarative and policy-driven method for developing and executing optimization applications such as homing/placement and change management scheduling optimization [87].
- **Service design and creation (SDC):** The SDC offers tools, methods, and repositories for defining, simulating, and certifying system assets along with their corresponding processes and policies. These assets are categorized into four groups: resources, services, products, or offers. The SDC environment caters to a variety of users through shared services and utilities. Within the design studio, designers of products and services can onboard, extend, or retire resources, services, and products [154].
- **Active and available inventory (AAI):** The AAI offers real-time and historical views of a system's resources, services, products, and their interrelationships. It integrates data from multiple ONAP instances, BSS, OSS, and network applications, providing a comprehensive "top to bottom" view from end-user products to the underlying resources. AAI serves as a dynamic registry, continuously updated by controllers in real-time to support the flexibility of SDN/NFV. The metadata-driven nature of AAI allows for the rapid addition of new inventory types through SDC catalog definitions, eliminating the need for lengthy development cycles.
- **Common controller software development kit (CCSDK)/ SDN controller (SDN-C):** The CCSDK/SDN-C handle specific configurations for both the RAN and transport subnets of a network slice. When requested by SO from TN NSSMF, it sets up and configures the new transport network slice subnet instance (NSSI), including updating the transport network during network slice instances (NSI) reuse, activation/deactivation, and termination. Similarly, when invoked by the SO from RAN NSSMF, it configures/re-configures the existing RAN NFs for RAN NSSI or NSI reuse. Additionally, when policy triggers closed loop actions in RAN for RAN NSSIs, it sends relevant configuration updates to the Near-RT RICs [87], [154].
- **Controller design studio (CDS):** The CDS framework provides blueprint definitions and archives for configuration management processes. It comprises a graphical user interface (GUI) and run time components. The GUI manages user input and displays both design time and

run time activities. It facilitates the creation of controller blueprints, including selecting design guidelines, incorporating artifact templates, and adding components. For run time, it allows user to direct the system to resolve the unresolved elements in the blueprint and downloads the resulting configuration into a VNF. It also enables the creation of data dictionaries, capabilities catalogs, and controller blueprints. The primary role of the Controller Design Studio is to generate and populate a controller blueprint, create a configuration file, and download it to a VNF/PNF [153], [154].

- **Data collection, analysis and event (DCAE):** DCAE, in collaboration with other ONAP runtime components, provides closed control loop automation, delivering FCAPS functionality. DCAE plays a key role in gathering performance, usage, and configuration data, conducting analytics computations, aiding in troubleshooting, and disseminating events, data, and analytics to entities like policy, orchestration, and the data lake. Working with the policy framework and closed loop automation management platform (CLAMP), these components detect network issues and suggest appropriate remediation. Actions can be automatic or trigger notifications to the SO or controllers for intervention, as configured by the operator. The policy framework is expanded to include additional decision capabilities through adaptive policy execution [153].
- **Policy Framework:** The Policy Creation component focuses on handling policies, encompassing rules, conditions, requirements, constraints, attributes, or needs that require provision, maintenance, and enforcement. At a granular level, policies involve machine-readable rules for executing actions based on triggers or requests, considering specific conditions. This enables the rapid modification of policies by updating rules, facilitating the adjustment of technical behaviors without rewriting software code. Policy simplifies the management and control of complex mechanisms through abstraction [153].
- **External API:** The External API offers northbound interoperability for the ONAP platform, serving as an access point for third-party frameworks and facilitating interactions between operator BSS and relevant ONAP components. This abstracted view of the platform within the existing BSS/OSS environment eliminates the need for lengthy and high-cost infrastructure integration [87].

E. The Underlying O-Cloud and O-Transport Infrastructure

The underlying infrastructure of O-RAN comprises the O-Cloud sites, the cellular sites (which include the Regional Cloud and Edge Cloud Sites), and the transport network. The two cloud sites and cellular sites are used to host the O-CU, O-DU, and O-RU of an O-RAN slice, respectively. The transport network is responsible for providing connectivity between several virtual or physical NF of an O-RAN slice deployed at cellular and/or cloud sites. In this section, we provide a brief overview of these major components of the underlying infrastructure in the O-RAN architecture.

1) *Cellular Site:* A cellular network site refers to the locations of O-RUs, which may be colocated on the same

structure as the O-RU or situated at the base. Typically, the cellular network site is designed to accommodate multiple sectors, thereby supporting several O-RUs. These sites play a pivotal role in the O-RAN architecture, serving as the points of connection between the O-RAN architecture and the core network infrastructure. They facilitate the transmission of data, control signals, and synchronization information between the radio units and the O-DU. The cellular network sites are distributed uniformly or non-uniformly based on parameters such user density, network topology, and others. They are classified as Macro, Micro, Pico, and Nano cellular network sites.

2) *Cloud Site:* A Cloud Site denotes a tangible location equipped with Cloud Infrastructure resources, suitable for O-Clouds, and possibly accommodating other non-O-Cloud resources. O-Clouds are deployed at both Regional Cloud and Edge Cloud locations. These sites serve as centralized points for hosting VNFs, SDN controllers, and other cloud-native applications within the O-RAN architecture. The Regional Cloud provides broader coverage and higher capacity, while the Edge Cloud brings computational resources closer to the network edge, enabling low-latency and high-bandwidth services.

a) *Edge Cloud:* Edge Cloud refers to a site that facilitates virtualized RAN functions for numerous cellular sites, offering centralized functions for those sites. Depending on the operators use case, an Edge Cloud may cater to a vast physical area or a relatively small one in proximity to its cellular sites. Nevertheless, the sites served by the Edge Cloud must be sufficiently close to the O-RUs to meet the network latency requirements of the O-DU functions. This proximity ensures that communication between the radio units and the O-DUs occurs with minimal delay, enabling efficient and responsive network operations and service delivery.

b) *Regional Cloud:* Regional Cloud designates a site supporting virtualized RAN functions for numerous cellular sites across multiple Edge Clouds, offering extensive centralization of the functionality. The sites served by the Regional Cloud need to be sufficiently close to the O-DUs to fulfill the network latency requirements of both the O-CU and the Near-RT RIC. This proximity ensures that communication between the O-CU and O-DU, as well as the Near-RT RIC, occurs within the required latency thresholds. It enables effective coordination and optimization of RAN resources across a broader geographical area while maintaining operational efficiency and responsiveness.

3) *O-RAN Cloud Platform:* A cloud computing platform known as O-Cloud consists of physical infrastructure nodes that are compatible with O-RAN and may host Near-RT RIC, O-CU, and O-DU, along with supporting software and necessary management and orchestration services. An O-Cloud node is composed of a group of central processing units (CPUs), random access memory (RAM), storage, network interface cards (NICs), basic input and output system (BIOS), baseboard management controllers (BMCs), and accelerators, which collectively handle computationally intensive tasks [22]. Depending on the deployment scenario selected within an O-Cloud instance, the O-Cloud platform can virtualize various

NFs and thus take over RAN functions within the overall architecture. Further details on these aspects are provided in Section V.

4) *O-Cloud Notification API*: The O-Cloud notification interface facilitates event subscription for consumers like the O-DU, deployed within the O-Cloud environment. Through this interface, event consumers can subscribe to receive notifications and statuses from the O-Cloud. Additionally, the cloud infrastructure offers event producers, allowing cloud workloads to access notifications and statuses that may otherwise only be accessible within the infrastructure itself [22], [139].

5) *Transport Network*: In disaggregated O-RAN deployments, the O-CU and O-DU may be deployed in two different distributed O-Cloud sites. To enable communication between O-CU, O-DU and O-RU, networking infrastructure must extend across the cellular site and distributed O-Cloud sites through open and highly-reliable transport networks. The transport network and services encompass a broad spectrum, involving FH, MH, and BH, as well as NR, legacy LTE, and legacy universal mobile telecommunications system (UMTS) technologies. These services span the CP, UP, and management plane (MP), and are designed to support the operational needs of different operators and various E2E services or applications such as URLLC and eMBB. The transport network must exhibit high flexibility to accommodate various use cases and RAN designs. Each segment of the physical transport network may need to support multiple slices, diverse 5G services, and different 3GPP interfaces based on specific requirements.

a) *Fronthaul*: FH in O-RAN is defined as the connectivity in the RAN infrastructure between the O-DU and O-RU. Mobile interfaces associated for the FH include Control, User, Synchronization, and Management planes. O-RUs and the corresponding serving O-DUs are positioned in close proximity to satisfy the delay criteria linked with FH [155].

b) *Midhaul*: The MH network represents a logical segment within the transport network, enabling communication between O-DU and O-CU and facilitating the transport of 3GPP F1/W1/E1 interfaces. In cases where O-DU and O-CU function as a unified entity, these interfaces remain inaccessible, and the transport network lacks a MH component. Additionally, it provides inter O-CU communication supporting the transport of the 3GPP Xn interface. In situations where MNOs haven't implemented a split O-DU and O-CU RAN architecture, these interfaces must be supported in the BH.

c) *Backhaul*: In the O-RAN architecture, the BH connects the O-CU to the 5G mobile core. It has a CP and UP component to ensure a clear demarcation between customer user data and the 3GPP 5G CP. The associated CP interfaces N1, N2, N4 and Xn-c are multipoint interfaces between O-CU-CP, UPF and other 5G CN components. The UP interface is provided by N3 between O-CU-UP and UPF, N9 between UPF and UPF, and Xn-u between O-CU-UP and O-CU-UP.

IV. O-RAN NFs, NETWORK SLICING, AND SMO DEPLOYMENT OPTIONS

The NFs in the O-RAN architecture can be implemented as VNFs and/or PNFs that can be hosted by the underlying

O-Clouds and/or cellular network sites. The O-Cloud is an O-RAN Cloud Platform comprising both hardware and software components designed for executing O-RAN NFs in cloud computing environments. The hardware includes compute, networking, and storage components, possibly incorporating acceleration technologies to optimize performance for hosting O-RAN NFs. The software component of the O-Cloud provides open and well-defined APIs, facilitating the life cycle of an O-RAN slice and its associated NFs. It is worth noting that the software is independent of the hardware, allowing flexibility and openness in vendor selection and ensuring compatibility with O-RAN NFs from various software suppliers.

In either scenario, whether the NFs are virtual or physical, they must be mapped onto appropriate hosts within the O-RAN infrastructure. The mapping of NFs onto underlying infrastructure is a crucial decision in the implementation of logical network functionalities of an O-RAN slice, especially in cloud computing environments. The deployments can range anywhere from fully distributed to maximally centralized configurations based on Edge and Regional O-Cloud sites (or the so-called PoP in ETSI terminology). The decision entails determining the optimal execution location for each logical function, with potential impacts on performance, scalability, cost, and other crucial factors. In this regard, the O-RAN Alliance has introduced the O-Cloud architecture and outlined several deployment scenarios for O-RAN NFs within the cloud-native architecture in [145]. Moreover, the document highlights numerous considerations essential for deploying logical NFs across different O-Clouds. The diverse slicing and NF deployment options within O-RAN require a range of management and orchestration solutions, leading to the multiple deployment options for the SMO Framework.

In the subsequent subsections, we delve into multiple deployment alternatives for O-RAN NFs, aligning them with the underlying infrastructure. Furthermore, we examine diverse network slicing deployment possibilities within the O-RAN architecture. Additionally, we shed light on various deployment choices concerning the SMO Framework, emphasizing the significance of network slice MFs.

A. O-RAN NF Deployment Scenario

The O-RAN Alliance has considered various options for virtualizing the O-RAN NFs in Regional and Edge Clouds proposing different deployment scenarios that can be supported by the O-RAN specifications. These deployment scenarios can be distinguished by a particular grouping of functionality at different key locations, such as cellular sites, edge clouds, and regional clouds, as well as by an indication of whether the functionality is provided at a particular location by an O-RAN PNF based solution, where software and hardware are tightly integrated and share a single identity, or by cloud services. In Figure 6, we illustrate several NF deployment scenarios presented in [145], [156], [157], where on the top, it shows the NFs and each scenario exhibits how these NFs are deployed, as cloudified NFs on O-Cloud or as PNFs at the cellular site. Each of these deployment scenarios will be explained below in detail.

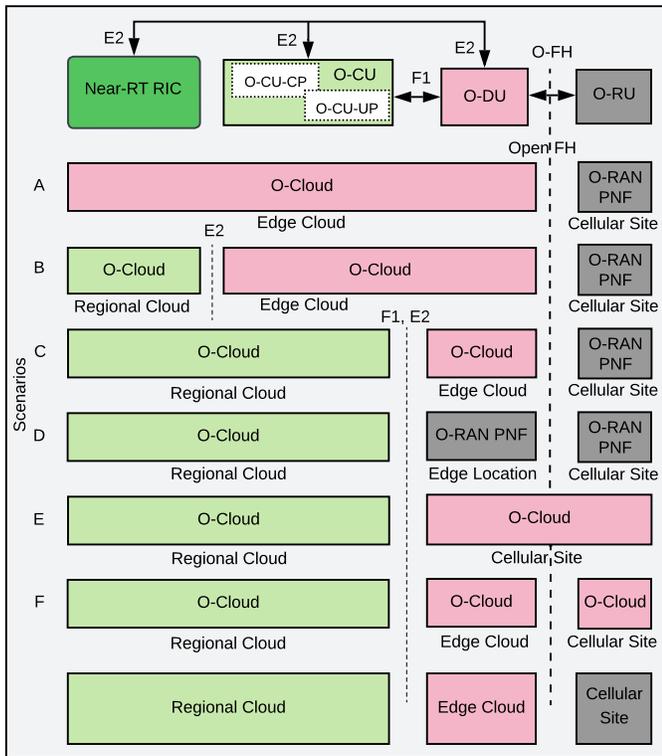

Fig. 6. O-RAN NFs deployment scenarios onto the underlying O-Cloud sites and ceullular network sites

a) *Scenario A:* In this scenario, the Near-RT RIC, O-CU, and O-DU are deployed at the Edge Cloud as VNFs, whereas the O-RUs are deployed on cellular network sites. This scenario is ideal for dense urban deployments with ample FH capacity, enabling the pooling of BBU functionalities at a central location. It reduces latency but comes with potentially higher deployment costs compared to other scenarios.

b) *Scenario B:* In this deployment scenario, the O-CU and O-DU are deployed at the edge cloud site in order to reduce latency, while the Near-RT RIC is deployed at the regional cloud site in order to gain a wider network perspective for performance optimization.

c) *Scenario C:* In this deployment scenario, the O-CU is co-located with the Near-RT RIC in the Regional O-Cloud site, and the O-DU is positioned at the Edge O-Cloud site. This scenario is tailored to support deployments in areas with limited remote Open FH capacity, imposing restrictions on the number of O-RUs. Two additional variations, C.1 and C.2, have been introduced to address the specific requirements of certain network slice instances [145], [157].

d) *Scenario D:* This deployment scenario is akin to Scenario C (see above). However, the O-DU is deployed as PNF at the Edge O-Cloud site in this scenario.

e) *Scenario E:* This deployment scenario mirrors Scenario D, with the key distinction that all components, including both O-DU and O-RU, are fully virtualized within the same Edge Cloud. This approach is being considered for future use, acknowledging that the virtualized versions of the low-PHY layer and other O-RU aspects are not currently available.

f) *Scenario F:* This deployment scenario involves the virtualization of both O-DU and O-RU, but they are hosted on separate O-Cloud sites. Like Scenario E, this scenario is

also considered for future use for a similar reason.

In the context of O-RAN deployment, the Open FH plays a pivotal role, delineating the separation between VNFs deployed within the O-Cloud and the Cellular network sites. O-RUs always occupy the Cellular site, while O-DU can be located at the Edge Cloud site. It is feasible to relocate O-DU closer to the Cellular site to adhere to maximum delay requirements, but extending their placement farther from the Cellular sites could potentially violate RAN internal and/or RAN service-specific timing constraints [156]. A common deployment scenario involves moving O-DU instances towards or even to the Cellular site together with O-RU, especially when the Edge Cloud site must be closer to the Cellular Site due to factors like fiber availability or other constraints. However, such adjustments may compromise the advantages associated with centralization and pooling [122].

The placement of O-CU and its associated UPF is determined by the lower latency of the F1 interface or service-specific constraints. For example, the placement of O-CU-UP and UPF for URLLC services would have to be limited to the Edge Cloud site while for eMBB it is viable to place at Regional Cloud site. Further, for services without specific latency targets, the corresponding O-CU-UP and UPF can be situated even in the Core Cloud site [145]. It is observed that centralizing O-DU proves most beneficial in densely populated networks where multiple Cellular network sites fall within the latency limits between O-RU and O-DU. On the other hand, sparsely populated areas are more likely to be handled by centralizing the O-CU alone.

B. Network Slicing Deployment Options in O-RAN

The concept of network slicing revolves around establishing a logical E2E virtual connections between end users or vertical customers and their desired applications and services [65]. This is achieved by allocating sufficient network resources to ensure that the services or applications can function properly and meet the specified QoS and predefined SLA requirements [67]. Network slicing provides the benefits of flexibility and scalability, enabling the creation of multiple secure logical networks that are isolated from each other but utilize the same physical network infrastructure [158], [159]. By utilizing the software and hardware disaggregation concepts with NFV technology, network slicing in O-RAN architecture enables service providers to maximize the usage of network resources and service flexibility [160].

The slicing architecture is structured into three distinct layers: the infrastructure layer (IL), network function layer (NFL), and service layer (SL) [64], [161]. The IL encompasses the entirety of the physical network infrastructure, comprising both RAN, CN, and transport network components. This layer is responsible for the deployment, control, and management of the infrastructure, as well as the allocation of computing, storage, network, and radio resources to network slices. Additionally, it manages how these allocated resources are made available to higher layers. The NFL encompasses all activities associated with configuring and managing the lifecycle of NFs including both physical and virtual. These functions are placed on the virtual infrastructure and interconnected to deliver an

E2E service that adheres to specific constraints and requirements defined in the service design of an network slice. The SL deals with the description of services and their mapping onto the underlying network components. It also encompasses the architectural aspects of slicing managers and orchestrators. This layer plays a critical role in defining how services should be articulated and connected to the underlying network elements, facilitating efficient network slicing operations [10].

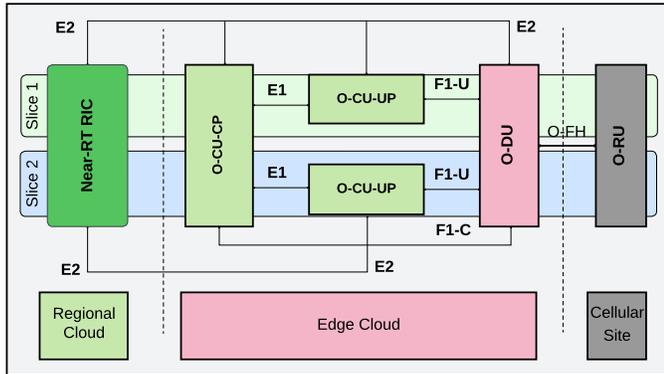

Fig. 7. O-RAN Reference Slicing Deployment Option

Deciding how to allocate specific logical functions to particular O-Cloud platforms, and consequently determining which functions should be co-located with other logical functions, is essential for the implementation of network slicing in O-RAN architecture [136]. The O-RAN components that can be shared with multiple slices are the Near-RT RIC, O-CU-CP, O-DU, and O-RU. The components which is meant to be dedicated for each network slice is the O-CU-UP. The method by which the NF are mapped to the same or distinct cloud platforms must be taken into consideration in order to build agreements with requirements for each deployment scenario [31].

One of the many potential deployment methods proposed by the O-RAN Alliance for O-RAN slicing is represented in Figure 7, where the O-RU is deployed at a cellular network site as a PNF. A Regional cloud site virtualizes the Near-RT RIC. The O-CU, and the O-DU are virtualized on a location-independent Edge cloud site. The O-CU and the O-DU are connected to the Near-RT RIC with the E2 interface, and the O-CU and O-DU are connected through the F1 interface. The Near-RT RIC, O-CU, and O-DU may be virtualized in several ways in the Regional and Edge cloud sites, as shown in Figure 6. For instance, an individual dedicated O-DU could be created for all network slices instead of sharing a common O-DU for all network slices in the deployment scenario illustrated in Figure 7.

It is important to note that the application requirements for the PNFs, cloudified network services, or O-Cloud platform might vary depending on the situation. However, the needs for the logical network functions will always remain the same [52], [145]. For Example, in this specific scenario, a single O-CU-CP instance governs the control of both network slices, while each network slice has its distinct O-CU-UP instance. If the UE is connected to both network slices, there will be only one RRC connection responsible for handling handover procedures and cell assignments through the shared O-CU-CP. However, each service belonging to a different NSI can

experience personalized QoS management and independent flow control through an individual SDAP/PDCP stack within its dedicated O-CU-UP [52].

Within the O-RAN slicing-aware architecture, the SMO Framework accommodates a Slice MF block containing 3GPP-defined NSMF, NSSMF, and NFMF. It also incorporates additional MFs specified by the ETSI ISG NFV and/or the MFs from the ONAP. In the following section, we will thoroughly explore different deployment options for SMO Framework within the context of network slicing management.

C. SMO Framework Deployment Options

As we discussed in Section III, the SMO Framework is responsible for the management and orchestration of O-RAN components and resources [22]. We also discussed in Section III that the SMO Framework can consist of management components and systems of various SDOs. To this date, various SMO Frameworks have been available in the market, claiming that they are compliant with the latest specifications of the O-RAN Alliance. However, their internal architectural frameworks and operational mechanisms are not accessible to the general public and hence they lack transparency and openness in terms of their features and functioning [19].

The O-RAN Alliance proposed two open-source solutions, the ONAP and the NFV-MANO, as comprehensive platforms intended to autonomously manage and orchestrate tasks associated with virtualized and software-driven elements and resources within the O-RAN architecture. The ONAP stands out as a prominent project that is in development and maintenance by the LF. Its association with the LF enables the ONAP to seamlessly integrate with significant projects like Kubernetes, Akraio, Acumos, and OpenDaylight [152]. The ONAP is already in use by the OSC as the preferred SMO platform for open-source O-RAN code releases [162].

On the flip side, the open source MANO (OSM), based on the NFV-MANO, is defined by the ETSI and follows the ISG on NFV specifications. The OSM offers comparable SMO services in a more lightweight framework than the ONAP. Additionally, it is notable that in May 2021, the ETSI initiated a cooperation agreement with the O-RAN Alliance, indicating the early stages of efforts to integrate the OSM framework within the O-RAN architecture [163].

In the rest part of this subsection, we examine the deployment scenarios and their potential effects of NFV-MANO and ONAP on network slicing architecture, as elaborated in [52].

1) *3GPP and NFV-MANO-based SMO Deployment*: The deployment options of the SMO Framework, in harmonization with both the 3GPP and NFV-MANO frameworks, emphasize the fundamental principles and prerequisites of network slicing. This encompasses the virtualization and softwarization of RAN resources and components, alongside the seamless integration of AI/ML capabilities and programmability within the SMO Framework.

This deployment option combines the slice MFs and network MFs defined by the 3GPP with those functional blocks defined by the ETSI ISG NFV. The NFV-MANO is responsible for managing and orchestrating VNFs, defining the processes such as the automation, management, and operation

of virtualized functions running on top of a virtualization and multi-tenancy-supporting infrastructure. Figure 8 illustrates the proposed deployment scenario incorporating 3GPP-defined slice MFs (such as the NSMF, NSSMF, and NFMF) alongside the NFVO and VNFM functional blocks defined within the NFV-MANO. These MFs and functional blocks of both the 3GPP and ETSI have been described in Section III.

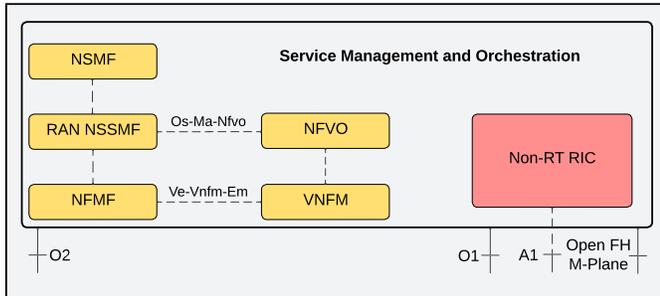

Fig. 8. The 3GPP and NFV-MANO-based SMO deployment option with a particular emphasis on O-RAN slicing

Furthermore, the O-RAN study group proposed four different possibilities in [31] for the deployment of the SMO Framework with respect to network slice management topology and their possible effects on O-RAN slicing-aware architecture. These four possible options for the deployment of the SMO Framework are explained in the following:

- Deployment Option 1: In this option, the network slice MFs (i.e., the NSMF and NSSMF) are deployed within the SMO Framework, as shown in Figure 8.
- Deployment Option 2: In this option, both the NSMF and NSSMF are deployed outside the SMO Framework.
- Deployment Option 3: This deployment option deploys the NSMF within the SMO Framework and the NSSMF outside the SMO Framework.
- Deployment Option 4: This deployment option involves positioning the NSMF out of the SMO Framework, while the NSSMF is implemented inside the SMO Framework.

The above-mentioned deployment options solely vary in the placement of the slice MFs as defined by the 3GPP. Within the scope of the O-RAN architecture, the RAN NSSMF, including its interactions with the SMO Framework, is the primary focus of the O-RAN Alliance [31]. During the creation and provisioning of RAN NSSI, the RAN NSSMF, in collaboration with the SMO Framework, triggers the instantiation of essential O-RAN functions, such as the Near-RT RIC, O-CU-CP, O-CU-UP, and O-DU, according to slice requirements. Following the establishment of RAN NSSI, RAN NSSMF can execute procedures for NSSI modification and deletion in coordination with the SMO Framework [52].

Each RAN NSSI is identified through the use of the network slice selection assistance information (NSSAI). The NSSAI includes one or a list of single NSSAIs (S-NSSAIs) that provide a distinct identifier to each RAN slice [164]. A S-NSSAI is a combination of two values. The first value is a mandatory slice/service type (SST) field, which identifies the slice type and consists of 8 bits within the range of 0-255. The SST may have a standard value such as eMBB, URLLC, or a network-specific value. The second value is

an optional slice differentiator (SD) field, which differentiates among slices with the same SST field and consists of 24 bits. According to [164], the list can include at most 8 S-NSSAIs, which means a single UE can be connected to at most eight RAN slice subnet instances at a given time.

2) *3GPP and ONAP-based SMO Deployment*: In Section III, it is elaborated that the ONAP framework provides the necessary management, orchestration, and automation capabilities to an E2E network architecture. The OSC employs the SMO Framework based on ONAP in conjunction with other OSC components [165]. Particularly noteworthy is the fact that Non-RT RIC, functioning at a parallel level with SMO, can utilize ONAP components for efficient A1 policy management in its implementations [83]. The ONAP encompasses workflows and user interfaces tailored for the network slice orchestration functions defined by the 3GPP notably CSMF and NSMF, along with an additional interface to an external NSSMF for the RAN, CN, and TN subnets. These slice MFs empower the ONAP framework to allocate an E2E NSI comprising suitable instances for RAN, CN, and TN NSSIs to meet the service-specific requirements [87].

The ONAP-based architecture suggests two possible deployment options in the Kohn release, emphasizing enhanced integration with the O-RAN architecture, improvements in cloud-native NF orchestration, and the advancement of intent-driven closed-loop autonomous networks [86].

In the first deployment option, the RAN NSSMF is placed within the SMO Framework, which is responsible for the management and orchestration of the RAN network slice subnet, including the O-RAN NFs and the related O-RAN TN components. This includes the FH between O-RU and O-DU and the MH interface between O-DU and O-CU. The RAN NSSMF determines the slice-specific configuration of O-RAN NFs based on the slice profile received from the NSMF and determines the necessary slice-specific requirements for the FH and MH interface, triggering TN management domain (MD) to execute the actual configuration of the FH and MH interface. For TN management and orchestration, the ETSI zero touch network and service management (ZSM) based MD approach is adopted [52], [87].

In the second deployment option, the NSMF is responsible for the determination of a slice profile of the FH, MH, and RAN NFs. The NSMF is also responsible for stitching together E2E network slice instances, including the FH and MH. Additionally, for both deployment options of RAN and TN subnets, separate RAN network slice subnet templates (NSSTs) are designed [87].

Figure 9 illustrates an expanded iteration of ONAP, as we showed in Figure 5 and discussed in Section III, incorporating O-RAN network slicing functions. The 5G E2E network slicing scenario requires the integration of several modules within ONAP, including the SDC, SO, AAI, UI, EXT-API, OOF, and Policy Framework. In the following, we provide detailed explanations for each of these modules.

The UI offers a range of functionalities to users. In the CSMF portal, users can create communication service forms to establish network services that use a network slice, view these services in a list, and perform operations like activation,

deactivation, or termination. Within the NSMF portal, network operators can find and manage slicing-related tasks initiated by customers, execute appropriate actions based on task status, and verify or modify slice options suggested by the OOF. Additionally, the NSMF portal enables users to display and process existing network slices, NSIs, and NSSIs through its slicing resource management feature [166].

Ext-API produces a *Service Order ID* and transmits it within the response, which can subsequently be utilized to monitor the order. Following this, Ext-API activates the API of SO to initiate the service creation process. This action represents progress in establishing uniform external interfaces for network slice orchestration [87], [166].

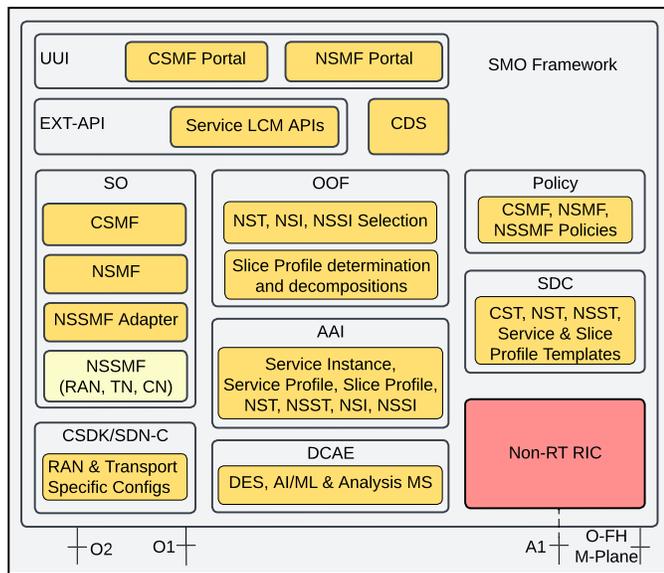

Fig. 9. 3GPP and ONAP-based SMO Deployment Option with a particular emphasis on O-RAN Slicing

Within the SO, distinct business process management notation (BPMN) workflows are established for the CSMF and NSMF. The CSMF workflow manages service requests originating from the CSMF portal and stores order information in a communication service instance within the AAI. The CSMF workflow then interacts with the NSMF workflow to initiate network slice requests. Subsequently, the NSMF generates service profiles, NSI, and NSSI. Both the NSI and NSSI can be shared [87].

The SO interacts with the OOF for the selection of network slice template (NST) and NSI/NSSI. The OOF may recommend either creating new instances or reusing the existing ones. Regarding NSI/NSSI selection, the OOF could return an existing NSI if it is shareable and a suitable one exists, an existing NSSI if shareable and no NSI exists but a suitable NSSI does, or a slice profile if the service request is non-shareable or no suitable NSI or NSSI exists. The recalibration of NSI and NSSI selection is managed by the orchestration task, which allows network operators to intervene manually through the NSMF portal in UI [166].

An NSSMF adapter incorporated in SO interacts with internal or external NSSMFs for NSSI orchestration. The NSSMF functionality includes a common part for subnet capability queries from SO, invoking domain-specific NSSMF functions

for the RAN, CN, and TN domains. The specialized workflows of the domain-specific NSSMF handle the essential tasks involved in creating or updating the NSSI according to the guidance provided by the OOF, particularly for NSSI creation or reuse [87].

The AAI module introduces three additional nodes, namely Communication-service-profile, Service-profile, and Slice-profile, along with modifications to the service-instance nodes. Three new nodes have been incorporated as attributes of the service-instance node. To align with SDC templates such as communication service template (CST), Service Profile Template, Slice Profile Template, NST, and NSST, the runtime instances include communication service instance (CSI), Service Profile Instance, Slice Profile Instance, NSI, and NSSI. The Slice Profile Instance for the all three subnets: RAN, CN, and TN are distinct [86], [87].

The AAI offers query APIs to CSMF and NSMF, enabling them to retrieve various information such as communication service instances, service profile instances, NSI, and NSSI. Additionally, AAI provides creation APIs to SO, allowing the creation of communication service profiles, service profiles, slice profiles, and establishing relationships between service instances [87].

The CCSDK/ SDN-C configures the RAN NFs when invoked by RAN NSSMF for RAN NSSI creation or reuse more details are provided in ONAP architecture subsection in Section III. The details of RAN configuration are obtained from the Config DB/configuration persistence service (CPS).

The DCAE introduces two new micro-services [166]:

a) **Data exposure service (DES)**: This micro-service offers a simplified interface for network operators, slice tenants, or any other ONAP component to query both current and historical PM/KPI data.

b) **Slice Analysis MS**: This micro-service carries out two distinct functions. Analyze PM received from the RAN through the PM-Mapper micro-service to detect any updates. When it receives configuration updates, it initiates a Control Loop by transmitting a suitable data movement as a platform (DMaap) message to Policy Framework.

V. SLICING THE UNDERLYING INFRASTRUCTURE IN O-RAN ARCHITECTURE

The evolving landscape of cellular network architectures, especially the transition from traditional D-RAN to C-RAN paradigms, signifies a fundamental shift in how underlying wireless infrastructures are conceived and deployed within the context of O-RAN architecture. The emergence of O-RAN architectures marks a significant departure from the conventional RAN model, emphasizing a centralized approach to key processing functions, notably the O-CU [167], which currently resides within centralized DCs. The decision regarding the placement of the O-DU, whether at the cellular site or further within a centralized DC, highlights the intricate considerations driven by network operators' preferences and operational needs [22], [42], [168].

At the heart of this architecture's efficiency lies the TN, responsible for ensuring seamless connectivity between the

cellular network site hosting the O-RU and the DCs on O-Cloud sites housing the VNFs (i.e., O-CU and O-DU) and service applications such as the RICs. Leveraging a diverse array of forwarding devices grounded in different technologies like the segment routing (SR) [169], dense WDM (DWDM), and microwave, the TN operates across various aggregation levels [170]. This facilitates the establishment of data paths encompassing different RAN and CN functions, thereby delineating distinct TN segments such as the FH, MH, and BH [51].

In this dynamic environment, the concept of network slicing emerges as a pivotal element within the underlying infrastructure of O-RAN. Integrated intricately into the disaggregated, virtualized, and open architecture of O-RAN, network slicing empowers operators to effectively manage resources and optimize performance in response to evolving demands [171]. Proficiency in network slicing within the O-RAN infrastructure not only ensures heightened operational efficiency and agility but also unlocks unprecedented opportunities for innovation and service differentiation [36]. This places the network operators at the forefront of the ongoing network evolution, spanning across 5G, 6G, and beyond, driving transformative changes in the wireless telecommunications industry.

In the rest of this section, we delve into the underlying infrastructure within the O-RAN architecture, including the components of the O-RAN cellular network site, the O-Cloud platform, and the Xhaul TN, examining the network slicing aspects of these critical elements.

A. O-RAN Cellular Site

In wireless communications networks, a cellular network site serves as a stationary stronghold where the complex interplay of radio signals takes place. It serves as a designated locus for transmitting and receiving radio signals, ensuring seamless coverage over a specified area. It encompasses two primary components: firstly, one or more antennas responsible for transmitting and receiving radio signals, and secondly, a supply unit housing essential switching and control elements critical for managing the operation of the antennas [172].

In the usual course of design, cellular network sites are structured to support numerous sectors, thus inherently associated with multiple O-RUs. The O-RU serves as a fundamental element in establishing seamless PHY layer connections with the UEs [22], [145]. Seamlessly, it brings together antenna elements and important RF components like transceivers and amplifiers. In addition, the O-RU also handles lower-level PHY tasks such as digital beamforming and fast fourier transform (FFT) operations [61]. The Open FH interface plays a crucial role in linking the O-RU with the O-DU to ensure smooth communication within the O-RAN architecture.

As detailed in Section IV, the process of optimizing the deployment of O-RAN entails navigating a delicate balance between FH latency and cost considerations. While consolidating all elements of the O-gNB at the cellular site minimizes latency, it also represents the most financially demanding option. Conversely, relocating control and connection anchors towards a centralized edge cloud facilitates resource management across multiple sites, all the while preserving the imper-

ative of low-latency data processing. Strategically relocating processing functions to the edge cloud while retaining only the O-RU at the cellular site achieves a harmonious equilibrium between minimizing latency and optimizing cost-effectiveness.

For services with less stringent time requirements, transferring the Near-RT RIC and O-CU to a regional cloud may result in increased latency, extending into the range of 50 milliseconds. However, this strategy optimizes resource processing capabilities across a network's various cellular sites. By centralizing these functions, a single Near-RT RIC can efficiently manage resource allocation while ensuring that critical processing units remain in closer proximity to users, enhancing overall network performance and responsiveness.

B. O-RAN Cloud Platform

One of the major objectives of the O-RAN Alliance is to enhance the flexibility and deployment speed of the RAN architecture while simultaneously lowering both capital and operating costs through the implementation of the underlying cloud architectures. The logical architecture of the O-RAN with the O-Cloud platform provides a fully open solution where software is decoupled from hardware.

Decoupling hardware and software within the O-RAN architecture entails a three-tiered approach: a hardware layer, an intermediary layer housing Cloud stack and acceleration abstraction functions, and a top layer dedicated to virtual RAN functions. These layers are capable of being supplied by different vendors, and this decoupling guarantees interoperability between a cloud stack and numerous hardware suppliers while also accommodating virtualized RAN functions from various software providers, thus defining it as an O-RAN Cloud platform or O-Cloud [145].

An O-Cloud platform, can automate and autonomously manage tasks with a certain level of complexity such as placing NF Deployment workloads on suitable O-Cloud nodes, executing self-repair, and auto-scaling based on deployment artifacts, and policies, without SMO intervention. An O-Cloud includes O-Cloud Resources, Resource Pools, and O-Cloud Services across multiple sites. It manages resource provisioning, Nodes, Clusters, and Deployments for both user-plan and management services, providing a unified reference point for all the elements within its boundary.

An O-Cloud Site refers to a collection of O-Cloud Resources at a specific geographical location, ranging from a single resource to thousands. These resources are interconnected through O-Cloud Site Network Fabrics, which serve as the demarcation for direct internal switching at the O-Cloud Site level. Multiple O-Cloud Sites can be interconnected to form a distributed O-Cloud, that requires bridging, routing, or stitching at the networking layer between each site and its respective external transport network attachment point [145].

The O2 interfaces serve as the conduit for connecting to a range of O-Cloud services offered by the O-Cloud platform in conjunction with the SMO Framework. These services are categorized into two main groups, each tailored to address specific functionalities and requirements within the O-Cloud ecosystem [128], [145]. Figure 10 depicts the primary components that constitute an O-Cloud site within the O-RAN

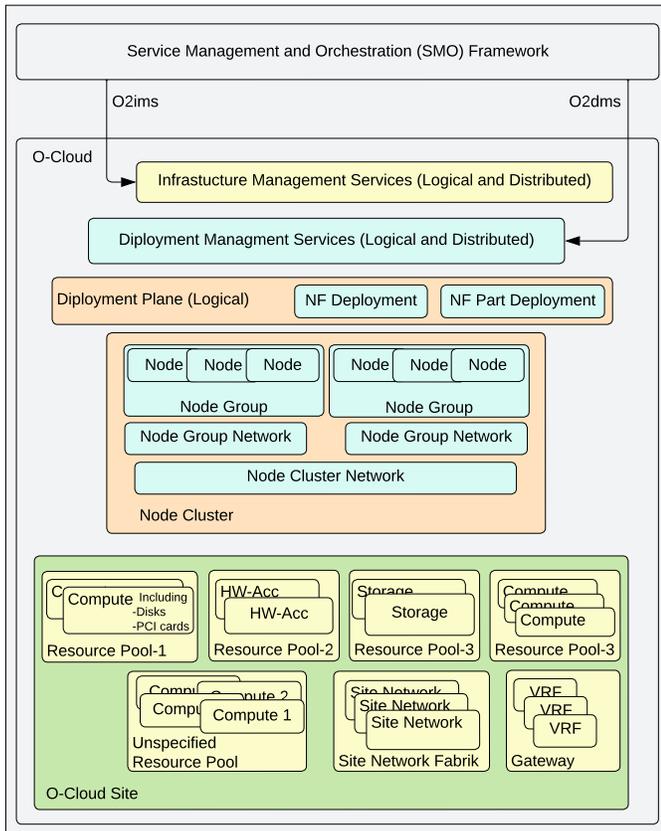

Fig. 10. Key components in an O-Cloud site with the O-RAN architecture. We now elaborate on each components in detail.

1) *Infrastructure Management Services*: Within the intricate framework of O-Cloud operations, infrastructure management service (IMS) form a pivotal subset of O2 functions, entrusted with the deployment and governance of cloud infrastructure. The IMS assumes an important role, facilitating provisioning by meticulously allocating and configuring resources for O-Cloud Node Clusters.

It manages fault and performance aspects, identifying issues and providing measurements through the O2ims interface. IMS exposes O-Cloud inventory that includes details on Sites, Deployment Management Services, Node Clusters, and Resources, aiding SMO in understanding allocation fulfillment and available capacities. The O-Cloud life cycle management involves registering, structuring, and configuring infrastructure services and resources. Additionally, it executes maintenance operations, such as switching O-Cloud Nodes to maintenance mode, autonomously or on demand, ensuring seamless communication with SMO Framework.

In the following, we delve into the concepts and perspectives entwined with O-Cloud IMS and the Cloud Infrastructure as elucidated in [145]:

a) *O-Cloud Resource*: This is a defined unit comprising capabilities such as compute, hardware acceleration, storage, and gateway within O-Cloud. These resources are provisioned and utilized for the O-Cloud deployment plane, enabling efficient allocation and management of computing resources in cloud-based network infrastructure.

b) *O-Cloud Resource Pool*: The O-Cloud Resource Pool consists of a grouping of O-Cloud Resources possessing

similar capabilities and traits within an O-Cloud environment. It comprises one or more such resources, each equipped with network connections and, optionally, internal hardware accelerators and storage devices. Additionally, it may include standalone servers lacking an associated O-Cloud Site Network Fabric, like infrastructure deployed at a cell site.

c) *Unspecified O-Cloud Resource Pool*: It refers to a collection of O-Cloud Resources listed in the O-Cloud IMS inventory but not yet categorized or allocated to any specific O-Cloud Resource Pool.

d) *O-Cloud Site Network Fabric*: It serves as an interconnecting resource within O-Cloud, linking various resources within a site to enable seamless communication and data exchange between them, enhancing overall functionality and resource utilization.

e) *O-Cloud Site Network*: It epitomizes a meticulously provisioned Network Resource, showcasing its defined capabilities and characteristics derived from an intricately configured O-Cloud Site Network Fabric.

2) *Deployment Management Services*: The deployment management service (DMS) efficiently handles various tasks by leveraging information received over O2dms. These tasks encompass the strategically placing O-RAN NF Deployment workloads within O-Cloud Node Clusters. Additionally, DMS manages the entire lifecycle of these workloads, including resource allocation, configuration adjustments, and the executing essential lifecycle management operations like autonomous scaling, self-healing, and workload relocation within the same O-Cloud Node Cluster to meet service level expectation (SLE). It also supervises the cessation of NF Deployments based on directives from the SMO. Furthermore, the DMS ensures the O-Cloud inventory is regularly updated with the latest status information on resources dedicated to NF Deployment workloads.

Below are the conceptual insights related to O-Cloud DMS and its interaction with O-Cloud Resources generated or modified via IMS provisioning as demonstrated in [145].

a) *O-Cloud Deployment Plane*: It refers to a conceptual framework comprising O-Cloud Nodes, O-Cloud Networks, and O-Cloud Node Clusters, which are pivotal components in constructing NF Deployments. This framework is established by leveraging O-Cloud Resources provisioned via IMS, derived from O-Cloud Resource Pools and O-Cloud Site Network Fabrics.

b) *O-Cloud NF Deployment*: NF Deployment refers to deploying software on O-Cloud resources to implement cloudified NFs, either fully or partially, facilitating NFV within cloud environments.

c) *O-Cloud Node*: It is a network connected computer or function, that can be provisioned into O-Cloud Node Clusters by IMS. The nodes comprises physical and/or logical components, and expose IMS-assigned resources to form O-Cloud Deployment Plane constructs. Additionally, an O-Cloud Node may operate independently as a standalone entity.

d) *O-Cloud Node Cluster*: It consists of a set of O-Cloud Nodes operating together via interconnected O-Cloud Node Cluster Networks. The Operating System and Cluster software

of these nodes identify their capabilities and characteristics managed by IMS.

e) O-Cloud Node Cluster Network: It denotes a dedicated network infrastructure tailored for an O-Cloud Site Network allocated to an O-Cloud Node Cluster.

f) O-Cloud Node Group: It refers to a subset of O-Cloud Nodes in an O-Cloud Node Cluster treated equally, particularly by the O-Cloud Node Cluster scheduler. These nodes are interconnected through O-Cloud Node Cluster Networks and optionally through O-Cloud Node Group Networks.

g) O-Cloud Node Group Network: It refers to the O-Cloud Site Network designated for a specific grouping of O-Cloud Nodes within an O-Cloud Node Cluster.

C. Xhaul Transport Network

The Xhaul TN in O-RAN encompasses diverse TN segments across the RAN and CN functions such as FH, MH, and BH. The Xhaul acts as the unified TN facilitating connectivity within and between the RAN and CN components. The TN, particularly the access TN like FH and MH, possesses the capability to concurrently handle diverse transport flows, particularly evident when operators integrate mixed-use cases into their RAN deployments.

Efficiently managing network resources becomes paramount due to the varied nature of these transport flows, each presenting distinct requirements in terms of latency, throughput, and transmission reliability [21]. This is essential to mitigate complexity and uphold optimal performance across the network. An astute strategy entails categorizing these transport flows into transport slices according to shared service prerequisites, thereby enabling more methodical and efficient management of the transport network. Subsequently, these slices may be subdivided into additional sub-slices as needed, tailored to accommodate a diverse array of E2E user applications or specific operator demands pertaining to priority, latency, or bandwidth allocations [170].

Embarking on the journey of seamless integration, the discussions within the 5G domain, especially in O-RAN, focus on incorporating network slicing into existing transport infrastructures [173]. Key questions arise regarding which mobile interfaces FH, MH, BH, and N6 require slicing, the forms these slices will take, and the optimal number of slices needed at the transport level.

In the subsequent sections, we will delve deeper into the architecture of the TN, exploring the complexities of TN slicing. This exploration aims to provide insights into the fundamental principles and practical considerations essential for the effective deployment and operation of Xhaul TNs in O-RAN environments.

1) Xhaul Transport Network Architecture: The Xhaul TN must exhibit a high degree of adaptability, as it needs to cater to different requirements based on the specific use case and RAN design. This could involve accommodating multiple network slices [28], numerous 5G services, and diverse 3GPP interfaces [170] across various segments of the physical transport network. O-RAN Alliance in WG9 transport requirements document [174] has meticulously outlined a multitude of prerequisites for the O-RAN TN, encompassing bandwidth

and delay projections within the 5G network, as well as the logical transport connectivity needs across FH, MH, and BH components and even the N6 portions of 5G.

In O-RAN Xhaul TN architecture, FH connects the O-DU and O-RU with a latency models based on eCPRI reference points [37]. MH enables communication between O-DU and O-CU with 3GPP defined F1/W1/E1 interfaces. While the BH network connects the O-CU to core network [170].

The deployment of an E2E Open Xhaul TN, which relies on packet switched transport solutions, is influenced by various factors. These factors encompass the extent of packet switching components, spanning from cell sites to the transport core, as well as the potential integration with other technologies in the FH to establish an E2E network [175]. Considerations also extend to the nature of the underlying Layer 0/Layer 1 transport, the network protocols implemented at the packet switching layer, and the framework for constructing overlay services on the Xhaul transport infrastructure.

Illustrated in Figure 11 is a unified E2E packet switched infrastructure, structured upon a dual split TN architecture that spans from cellular sites positioned at the edge of the access layer to the core of the transport layer. The packet switching transport network equipments (TNEs) exhibit QoS capabilities, boasting high capacity and low latency, interconnected via point-to-point Ethernet interfaces. Additionally, it integrates strategically distributed DCs throughout the transport network infrastructure to facilitate both virtual and physical NFs essential for mobile and fixed services. Furthermore, it offers the potential for hosting *Application Functions* geared towards providing value-added services and *custom applications* tailored to individual customers.

The diagram presents a conceptual depiction of the network, acknowledging that the actual physical implementation may vary. For instance, an O-DU could be linked to a single TNE port yet facilitate two logical connections to a second TNE in the FH network and a third TNE in the MH network. In contrast, some operators might opt to utilize packet-based technology solely in the MH and BH, while employing straightforward physical networking to connect O-DU ports with O-RUs. In such scenarios, the physical network between O-RU and O-DUs might consist of simple dark fiber links, or alternatively, operators may choose to implement a passive wavelength division multiplexing (WDM) system for added simplicity [170], [176], [177].

Within the O-RAN framework, the FH network plays a pivotal role in facilitating the remote transmission of signals from O-RU to O-DU. The O-RAN architecture brings forth novel requirements for FH networks, including considerations such as FH latency and data rate. WDM has emerged as a solution for addressing these challenges, offering various architectural approaches such as passive WDM, active WDM, and semi-active WDM. For more details on WDM, please refer to [176]

It is imperative to differentiate between the underlay/fabric of the transport infrastructure and the services that rely on it. The primary objective of the underlay is to establish a scalable environment capable of meeting the diverse service requirements of a 5G infrastructure. In contrast, the services

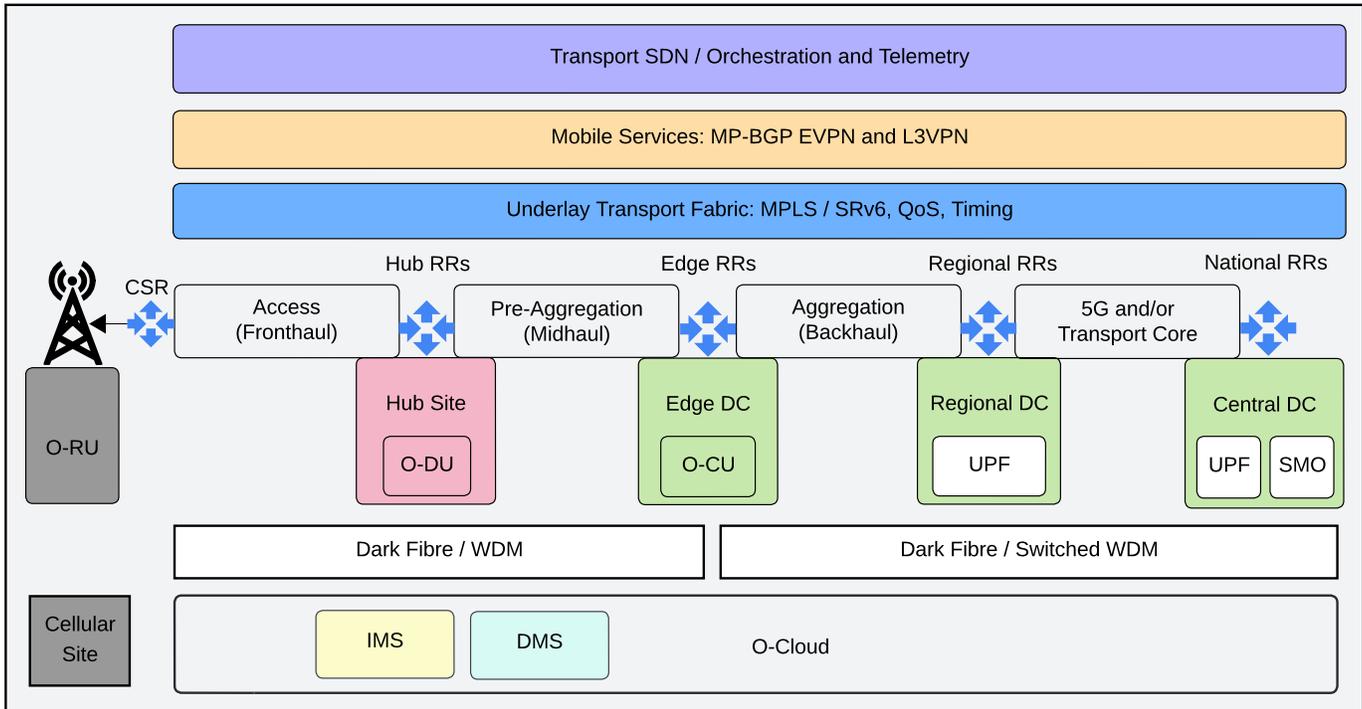

Fig. 11. Packet switched TN for Mobile Xhaul in O-RAN architecture

infrastructure, or overlay, operates above the underlay of the transport network, facilitating various components of the 5G infrastructure such as FH, MH, and BH [46], [170].

a) *Xhaul TN Underlay/Fabric Technologies*: The underlay networks encompass the physical infrastructure of a network, comprising DWDM equipment, ethernet switches, routers, and the fiber optic cabling that interconnects these components into a network topology. To support an Xhaul transport environment, the packet switched network must handle both layer 2 (L2) and layer 3 (L3) services. Presently, L2 underlay networks predominantly rely on Ethernet, often utilizing virtual LANs (VLANs) for segmentation. Within O-RAN, following two prevalent packet switched underlay technologies are explained in [170].

- **Multi-protocol label switching (MPLS)**: MPLS employs label switching in the data plane with multiple control plane technologies including SR an extension to interior gateway protocol (IGP) and border gateway protocol (BGP). Regardless of the MPLS control plane used, the service layer is independent and supports native Ethernet and L3 services [178].
- **SR over IPv6 (SRv6)**: SRv6 is based on the SR architecture and utilizes an IP version 6 (IPv6) data plane, where segments are identified by segment IDs (SIDs) embedded in the IPv6 header [179]. While sharing some similarities with SR-MPLS, there are key differences in requirements, especially concerning the critical aspect of scaling the underlay infrastructure in the context of a 5G environment.

The underlay is anticipated to offer a comprehensive set of tools necessary to deliver essential network services, encompassing functionalities such as universal connectivity, prioritization, isolation, scalability, rapid convergence, shortest path

routing, traffic engineering, packet-based QoS, and precise timing mechanisms [170].

b) *Xhaul TN Overlay/Services Infrastructure*: Overlay networks utilize network virtualization principles to create virtualized networks, consisting of overlay nodes like routers. These networks leverage technologies such as ethernet VPN (EVPN) and multi-protocol border gateway protocol (MP-BGP) based layer 3 VPNs (L3VPNs) for tunneling encapsulation within the overlay service layer. This encapsulation, facilitates the transmission of data packets over the underlying physical network while maintaining logical separation and isolation between different virtual networks or segments [170].

Both MPLS and SRv6 packet switched underlays utilize EVPN for L2 support and MP-BGP for L3VPNs. In the MP-BGP architecture, the protocol is configured with suitable address-family support for both EVPN and L3VPN, facilitating the transmission of service connectivity information among provider edge (PE) equipment [178].

Ethernet services will be provided by EVPN, where EVPN virtual private wire service (VPWS) acts as a transport service for Open FH and radio over ethernet (RoE), ensuring redundancy for Open FH interfaces. BGP L3VPNs support internet protocol (IP)v4 and IPv6, presenting flexible connectivity models with default shortest path routing, along with the option for automatic steering into SR policy [169].

Mobile IP services are set to be facilitated by MP-BGP based L3VPNs. These L3VPN services serves in establishing L3 connectivity among various mobile components. With the BGP L3VPN support, operators gain access to both IPv4 and IPv6 virtual private networks (VPNs), thereby enabling the adoption of flexible connectivity models to address a wide array of network requirements.

2) *Xhaul Transport Network Slicing*: In packet switched networks, there exists a robust framework poised to support

the intricacies of network slicing. Within the Xhaul transport infrastructure lies the inherent capacity to cater to the diverse transport demands of various interfaces. This extends not only to O-RAN but also encompasses interfaces defined by 3GPP, necessitating bespoke solutions for the control, management, and user plane interfaces. This entails the implementation of 5G transport segmentation from a mobile standpoint, wherein slicing at the FH, MH, and BH interfaces becomes indispensable [62], [180]. Slicing allows for the customization of resources to precisely match the specific latency, bandwidth, and traffic characteristics associated with each interface [181].

In the domain of TN, the concepts of *hard slicing* and *soft slicing* delineate the degree of isolation between network slices [182]. Hard slicing entails the allocation of resources exclusively to a particular NSI, ensuring stringent assignment and limited resource sharing. Conversely, soft slicing preserves the attributes of a transport slice but permits shared and reusable resources across different NSIs [62], [183]. This approach offers heightened flexibility and efficiency in resource utilization. Essentially, while hard slicing prioritizes exclusive dedication to individual slices, soft slicing fosters shared and reusable resources, thereby enhancing overall flexibility in resource management.

The functional architecture displayed in Figure 12 illustrates Xhaul TN slicing, incorporating orchestration infrastructure and encompassing the RAN, CN, and Xhaul TN. It seamlessly integrates NSSIs overlay and TN underlays, thus showcasing the system's comprehensive design.

Ensuring the flexibility of mapping NSIs to physical or logical transport network instances is paramount. This guarantees seamless alignment between the transport network and the unique requirements of each network slice, thus creating a dynamic and responsive infrastructure. The process of mapping NSIs to logical networks within an Xhaul TN heavily depends on the available deployment options [184]. Below, we elucidate some of these concepts as outlined in O-RAN WG9 documents.

a) *Transport Plane*: Within the O-RAN transport infrastructure, both L2 EVPN and L3VPNs leverage MP-BGP to establish individual NSIs. These VPNs provide exceptional scalability, supporting numerous instances and endpoints while offering diverse connectivity models. Additionally, four approaches are detailed for constructing the underlay transport plane/planes, each tailored to enhance network performance and meet specific requirements [170].

- **Single transport plane for all slices:** In this configuration, a single transport plane serves as the backbone for all network slices, facilitating a uniform distribution of traffic paths among them. Consequently, each slice traverses identical routes between network endpoints, fostering cohesion and consistency across the network infrastructure. This strategy is often considered the softest form of slicing within the underlay transport plane, as it prioritizes shared resources and harmonious coexistence among slices.
- **Transport plane per 5G service type:** Tailoring the underlay network to accommodate each 5G service type involves constructing dedicated transport planes, each

customized to suit the distinct forwarding behaviors associated with different services. These specialized transport planes are open for use by multiple customers who implement VPNs and traffic steering techniques.

Depending on various criteria, such as service requirements and network conditions, these transport planes can adopt unique topologies and optimizations. For instance, for URLLC service types, the focus may be on reliability, utilizing the most dependable links and selecting optimal paths based on link delay metrics. In contrast, eMBB service types may prioritize cost-effective, high-bandwidth links, determined by paths calculated with IGP metrics correlated with link capacity. For narrowband IoT (NB-IoT) service types, which do not necessitate low latency or high capacity, a separate transport plane could be designated, with paths established based on traffic engineering (TE) metrics, favoring links suitable for these specific services.

- **Transport plane per slice customer:** In this alternative approach, rather than allocating a transport plane for each 5G service type, a separate transport plane is assigned to individual customers. While similar techniques are employed, scalability is now contingent on the number of customers utilizing the network, as opposed to the diversity of 5G service types. To tackle scaling challenges, a combination of mapping per customer and per 5G service type can be implemented. As an illustration, the primary approach might entail mapping according to 5G service types, where only a selected group of premium customers receive dedicated mappings to individual transport planes.
- **Transport plane per 5QI group:** In this setup, the TN allows for the integration of traffic streams characterized by different 5G QoS identifier (5QI) values into specific slices. This configuration enables the straightforward allocation of a significant number of 5QIs to a limited pool of transport resources, such as queues located within TNEs. As a result, the network can efficiently manage and prioritize various types of traffic within these defined slices.

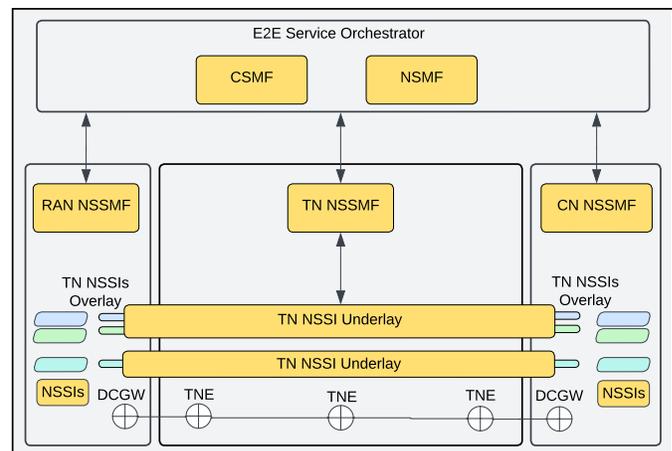

Fig. 12. Functional Architecture of TN Slicing

b) *Quality of Service*: In TN, QoS plays a critical role in ensuring that different types of traffic receive appropriate

levels of service, such as bandwidth, latency, and packet loss, to meet specific performance requirements. When it comes to slicing a transport infrastructure to accommodate different types of traffic or services, the significance of QoS becomes even more pivotal. Just as in the transport plane, different strategies can be used to provide varying levels of isolation between slices. These strategies may include traffic prioritization, bandwidth allocation, traffic shaping, and congestion management techniques [184]. When contemplating QoS within the context of TN slicing, it's crucial to consider both edge QoS solutions and core QoS solutions.

- **Edge QoS:** Edge interfaces within packet transport networks often experience delays and frequent congestion. In the context of network slicing, it's essential to enable traffic conditioning at the network's edge upon entry and scheduling upon exit to ensure each slice maintains its allocated bandwidth. Moreover, when mobile clients present traffic through VLANs, the PE router needs hierarchical QoS capabilities to effectively manage both the overall allocated bandwidth at the VLAN level and the designated class bandwidth within each VLAN.
- **Core QoS:** In the core network, various QoS strategies manage bandwidth allocation and queue sharing among different network slices, ensuring optimal performance and resource utilization.

c) *Service Models:* In addition to the physical components of the infrastructure, there is a necessity for establishing separate networks dedicated to managing and controlling various aspects of the 3GPP and O-RAN frameworks. These networks, known as management and control plane networks, play crucial roles in managing and regulating the functionality and performance of the networks [170]. Within the architecture designed for transport network slices, certain management networks operate as independent VPN entities. On the other hand, there are instances where multiple MFs are integrated within a single VPN entity. This consolidation allows for more efficient management and control by centralizing various tasks and functionalities within a unified network structure.

- **TN management network:** Each TNE is equipped with a local network management interface, complete with its unique IP address, facilitating day-to-day administrative tasks. This interface serves as the originating point for management protocols, seamlessly integrated into a transport management network utilizing an MP-BGP L3VPN, meticulously aligned with the default routing algorithm. The architecture of the TN management network is typically configured in an any-to-any topology, enabling seamless connectivity between all entities within L3VPN [185]. However, a more prevalent configuration involves a hierarchical structure where central network MFs maintain bidirectional communication with TNEs, while TNEs themselves are isolated from direct communication with each other.

Furthermore, Service Providers have the option to establish an out-of-band network in addition to the primary in-band management network, providing redundancy in situations where in-band network connectivity is com-

promised.

- **DC management network:** Distributed across the transport network, DCs necessitate centralized management to effectively support a plethora of *Network Functions* and *Application Functions*. Some of these functions are intricately tied to the provision of 5G and O-RAN capabilities and services. The management network of these DCs aligns with the O2 interface as defined by O-RAN, catering to a variety of DC management, monitoring, and orchestration needs. Each DC seamlessly hands off its management network to a TNE via a logical Ethernet interface, which is seamlessly integrated into an MP-BGP L3VPN on the TNE. This VPN serves as the conduit connecting all DCs to the central MFs.
- **O-RAN FH Management network:** The FH M-Plane interface serves as a specialized VPN spanning the TN, separate from the O-RAN Management and Control VPN that supports interfaces like O-RAN A1, E2, and O1. Mobile elements accessing the M-Plane are directed to link with the FH Management VPN via a logical Ethernet interface.
- **O-RAN Control and Management network:** The A1, E2, and O1 interfaces are seamlessly integrated into a singular VPN infrastructure spanning the entire transport network. Leveraging MP-BGP L3VPN technology, the O-RAN Control and Management network operates in alignment with the default routing algorithm of the underlying infrastructure. This network is imperative across all TNEs, established through VLAN attachment circuits (ACs), to provide support for O-RAN components utilizing the A1, E2, or O1 interfaces.
- **3GPP Control Plane network:** A consolidated 3GPP core infrastructure functions within a specialized 3GPP control plane VPN across the TN. This VPN efficiently handles all 3GPP control plane traffic concerning MH and BH operations, incorporating protocols like F1-C, E1, Xn-C, N1, N2, and N4 across various slices. Accessible on all TNEs through VLAN ACs, the 3GPP control plane VPN guarantees seamless connectivity for mobile components reliant on the 3GPP control plane.
- **O-RAN and 3GPP User Plane networks:** In the latest O-RAN slicing scenarios, the transport architecture has been refined to accommodate slicing in MH, distributed UPFs, and the relocation of the N6 network nearer to radio cellular sites. Each slice is now linked with a dedicated L3VPN, effectively managing both MH and BH user plane traffic. Moreover, the extension of the N6 network deeper into the transport infrastructure is essential to empower distributed and centralized UPFs, allowing access to shared applications and the utilization of local breakout functionalities.
- **FH C/U Plane network:** The FH components of O-RAN do not yet support slicing, resulting in O-RUs and O-DUs being utilized universally across all slices. A dedicated 7.2x eCPRI stream connects the O-RU and O-DU, overseeing all control and user plane traffic for each slice. The 7.2x C/U interface must be compatible

with Ethernet encapsulation and may optionally support Ethernet/IP encapsulation.

- **MH U-Plane network (F1-U, Xn-U):** To segregate F1-U traffic, individual VLANs are assigned to each user plane slice on both O-DUs and O-CU-UPs. QoS is maintained by these components, as they allocate a differentiated services code point (DSCP) value customized to the importance of the user payload within the GPRS tunneling protocol user plane (GTP-U) packet.

The user plane traffic for MH and BH, linked to a slice, utilizes a unified MP-BGP L3VPN, offering seamless any-to-any connectivity. Should an operator prefer to segregate MH and BH traffic, they have the option to employ distinct MP-BGP L3VPNs for each slice, ensuring separate routing for both types of traffic

- **BH U-Plane networks (N3 and N9):** User plane slicing in the BH network assumes that traffic associated with distinct slices originates from separate logical Ethernet interfaces on the BH interfaces of O-CU-UPs and UPFs. To maintain these slice mappings throughout the TN, VLAN ACs are allocated to different L3VPNs on the TNEs or DC-TNEs. Within the TN, MP-BGP L3VPNs can be established per slice or shared among slices, depending on how the mobile component presents the slice traffic to the TN. These L3VPNs are aligned with the underlay’s default routing algorithm or flex-algo, and TE can be employed to map L3VPNs to different underlay transport planes.
- **Data Network:** The N6 data network, although beyond the context of RAN, requires consideration for TN slicing, especially as it expands closer to the radio infrastructure with multiple breakout points. The methodologies discussed for BH and MH user plane slicing are largely applicable when establishing data networks over a shared packet switched transport infrastructure. When incorporating multiple breakout points in the data network, meticulous planning is essential to ensure the traffic exits and re-enters the network at designated locations. This entails strategic management of UPF addresses within the data network, as well as determining how these routes are externally propagated by routers at peering points, and how external routes are disseminated within the data network.

VI. EXPLORING USE CASES RELATED TO NETWORK SLICING IN O-RAN ARCHITECTURE

The exploration of network slicing within O-RAN encompasses deploying network slices for various use cases while also highlighting the diverse requirements of business customers seeking to realize their specific needs. These requirements may encompass ultra-reliable services, high-bandwidth communication, and low latency, among many others. The O-RAN Alliance has identified specific use cases for network slicing to showcase its potential in meeting the demands of business customers. In this section, we delve into several use cases outlined in O-RAN Alliance specifications, expected to be supported within the O-RAN slicing-aware architecture discussed in Section III. The requirements derived from these

use cases will be integrated into O-RAN as network slicing requirements. Prioritizing and specifying support for these use cases by the O-RAN community are essential, as not all of them have been realized in the O-RAN specifications yet.

TABLE III
ACTORS AND THEIR ROLES IN DIFFERENT STAGES OF O-RAN SLICE SUBNET MANAGEMENT AND PROVISIONING USE CASES

Actors	Activation	Modification	Deactivation	Termination	Configuration	Feasibility Check
NSMF	Yes	Yes	Yes	Yes	Yes	Yes
NSSMF	Yes	Yes	Yes	Yes	Yes	Yes
SMO OAM	Yes	Yes	Yes	No	Yes	Yes
NFMF	Yes	Yes	Yes	No	Yes	Yes
Near-RT RIC	Yes	Yes	Yes	Yes	Yes	Yes
O-CU-CP	Yes	Yes	Yes	Yes	Yes	Yes
O-CU-UP	Yes	Yes	Yes	Yes	Yes	Yes
O-DU	Yes	Yes	Yes	Yes	Yes	Yes
O-RU	Yes	Yes	Yes	Yes	Yes	Yes
O-Cloud M&O	No	Yes	No	Yes	No	Yes
Non-RT RIC	No	Yes	No	Yes	No	Yes

A. Slice Subnet Management and Provisioning Use Cases

The aspects related to the management and orchestration of network slicing, including NSI and NSSI, are provided by the 3GPP. The NSI refers to an instance of an E2E network slice, while the NSSI represents a part of an NSI, such as NSSI for the RAN domain or NSSI for the CN domain. For a comprehensive detailed discussion on the lifecycle management and provisioning of both the NSI and NSSI, interested readers may refer to [186]. In the use cases discussed in this subsection, we outline the most essential procedures for O-RAN Slice Subnet Management Provisioning, ensuring alignment with the 3GPP Slice Management framework and requirements [187]. The use cases further outline the steps involved in the different stages of the use case. These steps encompass *Creation, Activation, Modification, Deactivation, Termination, Configuration, and Feasibility Check* for O-RAN architecture. The use cases encompass a diverse array of actors, including O-RAN NFs and MFs designated as NFMS provider (NFMS_P), NSSMS provider (NSSMS_P), NSSMS consumer (NSSMS_C) at each stage with their respective roles [52]. Table III presents a comprehensive list of actors alongside the specific use cases requiring their involvement.

a) *Creation:* The objective of this phase is to establish the O-RAN NSSI (O-NSSI) or initialize the existing one to meet the RAN slice subnet requirements. This phase begins when the request for an NSSI is received by the NSSMS_P. It assesses the feasibility of the request by considering the

received requirements for the network slice subnet. NSSMS_P decides whether an existing O-NSSI can be used, which may trigger the modification phase, or a new slice subnet will be created. The VNFs within O-RAN will then be instantiated by a service request from NSSMS_P to O-Cloud management & orchestration (M&O). The response will then be forwarded to O-NSSI, which configures its constituents of O-NSSI using O-RAN NF provisioning service. After that, the NSSMS_P activates TN Manager to establish necessary links such as A1, E2, as well as FH and MH connectivity. The network slice subnet requirements are forwarded to the Non-RT RIC, and NSSMS_C will be informed about the resulting status of this process. This phase reaches its conclusion upon the establishment of the necessary O-RAN NFs and O-NSSI, alongside the configuration of the Non-RT RIC [52].

b) Activation: The goal of this phase is to activate the O-NSSI. This use-case has the pre-condition that an O-NSSI has already been created but is in an inactive status. This means that several O-RAN NFs may be contained in the O-NSSI but not yet have been activated. To begin the procedure, NSSMS_C sends a request to NSSMS_P to activate the O-NSSI. The NSSMS_P then identifies and decides to activate the parts that are inactive. For example, consider the elements listed in Table IV, where all the NFs are inactive since they are not shared with other O-NSSI, but Near-RT RIC is only activated for other services. NSSMS_P makes sure that all the constituents of NSSI are installed and activated on request of NSSMS_P. When all are activated, NSSMS_P receives a notification from NFMS_P and notifies NSSMS_C about the activation of the O-NSSI. It also changes the administrative state of the O-NSSI to unlocked. This process ends after the activation of O-NSSI or if one of the steps fails [52], [186].

c) Modification: The objective of this use case is to ensure compliance with O-RAN slice subnet requirements by refining the existing O-NSSI. The only prerequisite of this phase is that the VNF packages for virtualized O-RAN NFs, slated for incorporation into the O-NSSI, have been previously incorporated [52]. The process initiates upon receiving a request to modify an existing O-NSSI along with new requirements by the NSSMS_P. Subsequently, feasibility is assessed, leading to two potential outcomes. Should the requirements prove unattainable, the NSSMS_P informs the NSSMS_C of the status along with O-NSSI details. Conversely, the provided information is segmented into modification requests for each constituent of the O-NSSI. If there are additional O-NSSIs managed by other NSSMS_Ps, their respective NSSMS_Ps are notified of the modification via the primary NSSMS_P, thereby activating their O-NSSIs. Additionally, the NSSMS_P can sequentially initiate various required aspects as below:

- A service modification request to O-Cloud M&O, if the O-NSSI contains virtualized parts.
- NF provisioning service to reconfigure the O-NSSI constituents, if the O-NSSI contains NF instances.
- O-RAN TN Manager coordination, if the NSSI contains TN part to establish or modify necessary links and interfaces, such as A1, E2, FH, and MH.

Upon completion of the aforementioned steps, the Non-RT RIC is informed of the revised network slice subnet require-

ments and O-NSSI details by the NSSMS_P. Subsequently, akin to instances where initial requirements cannot be fulfilled, it notifies the NSSMS_C regarding the process status, along with pertinent O-NSSI information. This phase culminates with adjustments made to the O-RAN O-NSSI and associated O-RAN NFs, alongside the configuration of the Non-RT RIC with the updated slice requirements and O-NSSI specifics.

TABLE IV
THE O-RAN NFs, ALONG WITH THEIR CURRENT STATE, ARE REQUIRED TO SATISFY THE PREREQUISITES FOR ACTIVATION

NF	Installed	Activated
Near-RT RIC	Yes	Yes
O-CU-CP	Yes	No
O-CU-UP	Yes	No
O-DU	Yes	No
O-RU	Yes (as PNF)	No

d) Deactivation: This scenario involves deactivating a currently active O-NSSI. When NSSMS_C decides to deactivate the O-NSSI, it sends a deactivation request to the NSSMS_P, initiating the process. Subsequently, the NSSMS_P identifies the active components of the NSSI and proceeds to deactivate those components that are not shared. Below are examples of active, non-shared O-RAN NFs:

- The O-CU-CP NF constituent: To terminate the connection with the Near-RT RIC, the E2 interface connection will be deactivated. The E1 interface connection between the O-CU-CP and the O-CU-UP will be released.
- The O-CU-UP NF constituent: The E2 interface connection with the Near-RT RIC is scheduled for termination.
- The O-DU NF constituent: The process of terminating the F1 interface connection with O-CU and the E2 interface connection with Near-RT RIC has commenced.
- The O-RU constituent: The M-Plane interface connection with O-DU is initialized for the termination.

Once the NSSMS_P identifies the mentioned components, it requests the NFMS_P to deactivate them. The NFMS_P proceeds to set the *administrativeState* of each item to *locked*, thereby deactivating them accordingly. Upon deactivation of all active, non-shared NSSI constituents, the NSSMS_P is notified. To conclude the process, the NSSMS_P sets the *administrativeState* of the O-NSSI to *locked*. The process concludes with the deactivation of the O-NSSI.

e) Termination: This use case involves ending or dissociating an existing but inactive O-NSSI when it is no longer required. Upon receiving the termination request, the NSSMS_P has two options: Firstly, if the O-NSSI is shared, it will be dissociated via the modification use-case described earlier. Secondly, if the O-NSSI is non-shared, it will be terminated. If there are constituent NSSIs within the O-NSSI that are not directly managed by the NSSMS_P, it sends a request to other respective NSSMS_Ps, indicating that they are no longer needed. The NSSMS_P also requests termination from the O-Cloud M&O for the non-shared virtual O-RAN NFs that are no longer required. Additionally, it initiates the

coordination procedure with the TN manager and informs the Non-RT RIC about the termination of the O-NSSI. Finally, the NSSMS_P notifies the NSSMS_C of the resulting status, successfully concluding the termination process.

f) Configuration: This use case involves configuring or re-configuring an existing O-NSSI. The configuration of the O-NSSI and its constituents is initiated by the NSSMS_C by triggering the configuration process. Subsequently, the slice subnet configuration/re-configuration information is sent to the NSSMS_P, which breaks down the reconfiguration data. Each constituent undergoes configuration management preparation, and if managed by the NSSMS_P directly, it is configured accordingly. If the constituents are managed by other NSSMS_Ps, they get activated. Configuration requests are also sent through the NFMS_Ps for O-NSSI with constituent O-RAN NFs. The NSSMS_P then sends the outcome, which is based on the results received from configuration management, to the NSSMS_C, which may receive additional results from other configuration management service providers.

g) Feasibility Check: This use case assesses the possibility of provisioning an O-NSSI and confirms whether its requirements are attainable. The precondition is that the NSSMS_C has acquired or received the necessary requirements for the network slice subnet. To commence the process, if an O-NSSI meets the network slice subnet requirements, a request must be sent to the NSSMS_P from the NSSMS_C. The NSSMS_P then identifies the involved constituents and can seek information from the SMO and the Non-RT RIC regarding the fulfillment of requirements. Subsequently, it checks the availability of network constituents by submitting reservation requests to the O-Cloud M&O. The NSSMS_P may also request the TN Manager gather information regarding the feasibility of the TN links. The results, including information about reserved resources, are then provided to the NSSMS_C and hence conclude the process.

B. RAN Slice SLA Assurance

The 3GPP standards have laid the groundwork for a highly adaptable 5G infrastructure, facilitating the establishment and management of bespoke networks tailored to meet specific service demands across a wide spectrum of applications, services, and business verticals. These requirements, meticulously outlined through standardization endeavors, encompass critical performance metrics such as throughput, energy efficiency, latency, and reliability [118]. Network slicing, an all-encompassing feature that extends across the CN, TN, and RAN, must consistently uphold these stringent criteria throughout the entire lifecycle of a network slice, with a particular emphasis placed on the RAN architecture [160].

However, the dynamic nature of the RAN architecture poses a considerable challenge in maintaining consistent service quality for each RAN slice within the complex multi-vendor O-RAN environment [36], [129]. Addressing this challenge necessitates further in-depth investigation and rigorous standardization efforts to establish the requisite mechanisms and parameters for the RAN slice SLA assurance [115]. The SLA is a contract between the network service provider and the

customer, defining responsibilities and performance standards and setting clear service expectations [188].

Leveraging the open interfaces of O-RAN and cutting-edge AI/ML-assisted architecture offers promising avenues for implementing these mechanisms, paving the way for network operators to capitalize on the myriad opportunities presented by network slicing [187]. This groundbreaking innovation has the potential to fundamentally reshape how network operators conduct their business operations and introduce revolutionary new business models [160]. For instance, the O-RAN architecture and interfaces empower network operators to optimize spectrum resource utilization by dynamically allocating spectrum resources across slices in response to evolving usage patterns, thereby maximizing spectrum resource efficiency. The various stages of the use case are delineated as follows:

a) Creation and Deployment of RAN slice SLA Assurance Models and Control Apps: In this phase, the training and deployment of the model begin with the activation of an O-RAN slice. A prerequisite is that the connection between the Near-RT RIC and the Non-RT RIC must be established via the A1 interface, while the O1 interface is configured between the SMO and the Near-RT RIC. This phase involves multiple steps executed by the Non-RT RIC. Initially, it retrieves a RAN slice SLA from the SMO Framework, specifically the NSSMF, and then proceeds to collect performance measurements and enrichment information from external applications via the O1 interface. Following this, the Non-RT RIC performs a thorough analysis of the accumulated PMs and/or enrichment information through extended periods of monitoring, which significantly contributes to the model training process [160].

The Non-RT RIC takes charge of model training and procures RAN slice SLA assurance models. There exist two options for model training: either utilizing an AI/ML model or employing a control app. Should an AI/ML model be selected, it can be deployed internally for slow loop optimization or conveyed to the Near-RT RIC via the O2 interface for fast loop optimization. Conversely, if a control app is opted for, it can be deployed by the SMO to the Non-RT RIC for slow loop optimization or transferred to the Near-RT RIC for fast loop optimization. Finally, the updates to the model or control apps are implemented upon the Non-RT RIC receiving updates internally or from the Near-RT RIC via the A1 interface. This process culminates upon the deactivation of the RAN slice.

b) Slow Loop RAN Slice SLA optimization: The grand objective of this phase is to achieve slow loop RAN slice SLA optimization. The preconditions for this phase mirror those of the Creation and Deployment phases, with the added condition that the RAN slice SLA assurance model or control apps have already been deployed.

In this phase, the Non-RT RIC is presented with two options for slow loop optimization. It may opt to adjust the RAN configuration in accordance with long-term trends, utilizing data collected via the O1 interface. Alternatively, it may choose to develop A1 policies tailored to the specific requirements of the RAN slice SLA, incorporating inputs such as A1 feedback, O1 long-term trends, and operator-defined RAN intents.

In the next step of this phase, the SMO Framework updates

the slice configuration of the Near-RT RIC or the RAN nodes based on the instructions received from the AI/ML model or control app. Following this update, there are two possible outcomes: either the Near-RT RIC and the RAN nodes proceed to implement and execute the updated slice configuration, or the Near-RT RIC receives the updated A1 policies, enabling it to take control of the RAN nodes and provide feedback via the A1 interface to the Non-RT RIC.

c) Fast Loop RAN Slice SLA optimization: In this phase, similar preconditions to those of the slow loop RAN slice SLA optimization are applicable. The Non-RT RIC evaluates the necessity of formulating a policy to ensure slice SLA assurance for the Near-RT RIC slice. This evaluation is based on the RAN slice SLA requirements and/or operator-defined RAN intents. It also considers feedback from the Near-RT RIC via the A1 interface or long-term trends observed through the O1 interface, as well as enrichment information from external application servers.

Afterwards, the Near-RT RIC is furnished with slice-specific O1 configurations from the SMO Framework and A1 policies from the Non-RT RIC. It proceeds to collect PMs information via the E2 interface. These gathered PMs, combined with the A1 policies from the Non-RT RIC, undergo analysis by either the AI/ML model or the control app to direct the RAN nodes towards meeting the slice SLA. This sequence concludes upon the deactivation of the RAN slice subnet.

C. Multi-vendor Slices

This use case involves orchestrating multiple network slices, each incorporating the RAN components sourced from diverse vendors. For instance, network slice 1 utilizes O-DU and O-CU from vendor A, while network slice 2 employs components from vendor B, with O-RU from vendor C being shared between both slices [189]. This allows for the utilization of different slices tailored to distinct application scenarios, as each component offers unique specifications. While the implementation of this use case can vary, they all involve the utilization of a single O-RU, which may be connected to one or more O-DUs. To support multiple slices, the schedulers of the virtualized O-DU (vO-DU) and virtualize O-CU (vO-CU) must manage each NSI individually [129].

The vendor supplying vO-DU and vO-CU functionalities must possess a robust customized scheduler tailored for specific services. Moreover, effective coordination between the vO-DU and vO-CU is essential to allocating radio resources seamlessly in multi-vendor slices, ensuring conflict-free operation. The necessary coordination can be assessed based on service objectives and their implications for the O-RAN architecture [118]. For instance, the following three potential coordination strategies could be explored:

Case 1: The resource allocation between the vO-DU and vO-CU is provisioned with loose coordination through the O1/A1/E2 interface; each pair of the vO-DU and vO-CU is responsible for allocating radio resources to individual customers within the radio resources allocated by the Near-RT RIC and/or the Non-RT RIC.

Case 2: A moderate coordination where the resource allocation can be negotiated among slices or the vO-DU/vO-CUs

via the X2 and F1 interfaces, following provisioning through the O1/E2/A1 interface. The negotiation period is extended to several seconds, influenced by the periodic exchange of the X2 and F1 messages between the vO-CUs.

Case 3: A tight coordination through a new interface between the vO-DUs for adaptive resource allocation, which needs a more frequent negotiation.

The utilization of multi-vendor slices is applicable in scenarios involving RAN sharing. In such cases, two operators, labeled A and B, possess their respective vO-DU and vO-CU components from distinct vendors while jointly utilizing the O-RU component. However, the scenario involving the use of O-DU and O-CU components from different vendors within a single slice requires further examination [189].

Adopting a multi-vendor approach cultivates a resilient and adaptable network ecosystem, benefiting operators and end-users alike. Upon the successful implementation of multi-vendor scenarios, the anticipated benefits include:

a) Flexibility and time-to-market deployment: Numerous vendors offer virtualized RAN components like the vO-DU, vO-CU, and schedulers for different network slices. Network operators can thus select the most suitable components for each network slice, whether they prioritize high data rates or low latencies. This flexibility also enables network operators to introduce new services effortlessly, with the option to implement additional functions from different vendors without changing their existing setups and configurations [40].

b) Flexible deployment for RAN equipment sharing: In scenarios where multiple vendors aim to share RAN equipment and resources, challenges may arise concerning vendor selection and the placement of RAN functions. However, by addressing these challenges through collaborative use-cases, network operators can reach agreements on shared RAN equipment and resources, thereby optimizing capital expenditure (CAPEX) and OPEX [190] and potentially opening doors to further business investment opportunities.

c) Supply chain risks reduction: In scenarios where a vendor discontinues support for certain vO-DU and vO-CU functions due to business circumstances, network operators retain the ability to implement substitute vO-DU and vO-CU functions from different vendors within a multi-vendor framework. This proactive approach serves to alleviate potential risks to network operators' ongoing business operations, bolstering their resilience amidst market dynamics [189].

D. NSSI Resource Allocation Optimization

The increasing complexity of 5G networks, marked by the proliferation of millimeter-wave small cells and diverse services like eMBB, URLLC, and mMTC, poses challenges in dynamically and efficiently allocating resources among network nodes [12]. These services, realized as NSIs, exhibit varying characteristics such as high-speed data, ultra-low latency, and sporadic traffic patterns influenced by factors such as time, location, UE distribution, and application types.

To tackle the aforementioned challenges, the optimization of resources allocated to NSSI is crucial. Various scenarios, such as internet of things (IoT) applications running during off-peak hours or weekends and large events causing a surge

in data flow, are considered. The data collected from the O-RAN nodes serves as input to train an AI/ML model embedded within the NSSI, enabling proactive determination of traffic demand patterns for different times and locations across network slices. This approach facilitates the automatic reallocation of resources ahead of network issues, optimizing resource utilization, and ensuring flexibility in responding to diverse service requirements [129].

Implementing resource quota policies within RAN NFs, notably E2 nodes within their respective NSSIs, facilitates efficient management of resource allocation across diverse slices [118]. This flexibility enables the prioritization of resource distribution based on service importance, fostering effective resource sharing during periods of both abundance and scarcity. Premium service slices within an NSSI may receive a more substantial allocation of resources compared to standard or best-effort service slices, while emergency services also benefit from additional resource allocation during critical situations [68]. Acting as constraints for resource allocation, these policies aim to optimize resource utilization across slices. They are adaptable and can be tailored to specific requirements, such as analyzing past resource allocation failures evident in RAN node measurements. This ensures optimal utilization, mitigates historical trends, and minimizes resource inefficiencies.

The O-RAN entities involved in this use case are the SMO Framework, the Non-RT RIC, and the O-RAN nodes. The SMO Framework establishes the default NSSI resource quota policy, which acts as a parameter for optimizing resource allocation. Meanwhile, the Non-RT RIC gathers performance metrics from the O-RAN nodes, employs the AI/ML models to analyze historical data, predicts traffic demand patterns, and determines appropriate resource adjustments for each NSSI [52], [118]. Subsequently, the Non-RT RIC optimizes the NSSI resource allocation by adjusting attributes and updating cloud resources through the O1 and O2 interfaces, respectively. The O-RAN nodes facilitate performance data collection and configuration updates regarding the NSSI resource allocation via the O1 interface. They also facilitate management data collection.

The process of the NSSI Resource Allocation Optimization on the Non-RT RIC may encompass the following steps:

a) Monitoring: The Non-RT RIC monitors the RAN to collect data through the O1 interface and gathers RAN performance measurements from the RAN nodes.

b) Analysis & decision: The Non-RT RIC leverages an appropriate AI/ML model to analyze measured data and forecast future traffic demand for each NSSI within a specified time interval and geographical location. Based on this analysis, it determines the necessary actions to adjust resources such as the VNF resources and slice subnet attributes for the RAN NFs specifically the E2 Nodes within their respective NSSI at the designated time and location.

c) Execution: The Non-RT RIC executes operations through two sequential steps guided by model inference. Firstly, it adjusts slice subnet attributes via the OAM functions in SMO Framework, utilizing O1 interface to configure the E2 nodes. Secondly, it initiates a request to the O-Cloud M&O for

updating the O-Cloud resources via the O2 interface. The coordination of these steps is managed by the SMO Framework following recommendations from the Non-RT RIC.

VII. CONCLUDING REMARKS AND FUTURE OUTLOOK

In conclusion, the exploration of O-RAN architecture illuminates its transformative potential in the context of wireless network infrastructure. As the telecommunications landscape evolves to meet the demands of 5G, 6G, and beyond wireless systems, O-RAN emerges as a promising paradigm shift, offering flexibility, interoperability, and cost-efficiency in network deployment and management. Through our analysis in this survey paper, it becomes evident that O-RAN's disaggregated approach to network elements, enabled by open interfaces, automation, intelligence, and software-defined networking principles, fosters innovation and competition among vendors while reducing vendor lock-in. This not only spurs the development of diverse and specialized network functions but also empowers operators to tailor their networks to specific use cases and environments with greater agility and granularity through the deployment of network slicing at both network and management domains. In essence, while the journey towards realizing the full potential of network slicing in O-RAN may be fraught with challenges, the destination promises a network landscape that is more open, agile, and responsive to the evolving needs of wireless communication in the next decade.

To explore the topic of network slicing within the O-RAN architecture in a detailed manner, we presented its several aspects in this paper, including the architectural framework, network slice deployment options, management and orchestration procedures, and underlying infrastructure, among many others. We began by exploring the ongoing standardization activities within various SDOs and the efforts of the OSC with respect to the realization of O-RAN. Then, we discussed the O-RAN architecture with a special emphasis on network slicing, covering its SMO Framework, O-gNB functionalities, and underlying infrastructure. Next, we studied a number of deployment options for NFs and network slices within O-RAN, as well as several deployment options for the MFs and management systems within the SMO Framework. We then surveyed network slicing associated with the underlying infrastructure within the O-RAN architecture, covering slicing in the cellular network sites, O-Cloud sites, and transport networks. Finally, we addressed several use cases related to the deployment of O-RAN slicing.

Looking ahead, future research endeavors could extend the current work by exploring the potential of xApps and rApps within the O-RAN framework, delving into their capabilities for enhancing network intelligence, service orchestration, and resource optimization. The envisioned xApps and rApps may employ advanced ML algorithms to dynamically allocate resources, predict traffic patterns, and optimize performance for each network slice. Additionally, integrating AI and ML models into various optimization functions within O-RAN networks presents a promising avenue for improving network efficiency, performance, and user experience. By harnessing the power of advanced analytics and automation, future research initiatives can further unlock the transformative poten-

tial of O-RAN, propelling the evolution of telecommunications infrastructure into a new era of connectivity and innovation. We hope that the insights, together with the deep dive into the O-RAN slicing specifications, architecture, and interfaces, will provide more flexibility for O-RAN slicing deployment by using AI and ML models and xApps and rApps.

LIST OF ACRONYMS

3GPP	3rd Generation Partnership Project	DES	data exposure service
4G	fourth-generation	DL	deep learning
5G	fifth-generation	DMaaP	data movement as a platform
5GC	5G Core	DMS	deployment management service
5QI	5G QoS identifier	DSCP	differentiated services code point
6G	sixth-generation	DU	distributed unit
AAI	active and available inventory	DWDM	dense WDM
AC	attachment circuit	E2E	end-to-end
AI	artificial intelligence	eCPRI	evolved CPRI
AMF	access and mobility management function	EM	element management
API	application programming interface	eMBB	enhanced mobile broadband
ARC	aerial RAN CoLab	EN-DC	E-UTRA NR dual connectivity
BBU	baseband unit	eNB	evolved NodeB
BGP	border gateway protocol	ETSI	European Telecommunications Standards Institute
BH	backhaul	EVPN	ethernet VPN
BIOS	basic input and output system	FAPI	functional API
BMC	baseboard management controller	FB	functional block
BPMN	business process management notation	FCAPS	fault, configuration, accounting, performance, security
BSS	business support system	FDD	frequency division duplexing
BWP	bandwidth partitioning	FFT	fast fourier transform
C-RAN	centralized RAN	FG	focus group
CAPEX	capital expenditure	FH	fronthaul
CCM	CIS cluster management	gNB	next generation NodeB
CCSDK	common controller software development kit	GPU	graphics processing unit
CD	continuous deployment	GTP-U	GPRS tunneling protocol user plane
CDS	controller design studio	GUI	graphical user interface
CI	continuous integration	HLS	high layer split
CIR	container image registry	HMTC	high-performance machine type communication
CIS	container infrastructure service	IGP	interior gateway protocol
CISM	CIS management	IL	infrastructure layer
CLAMP	closed loop automation management platform	IMS	infrastructure management service
CN	core network	IoT	internet of things
CNF	containerized network function	IP	internet protocol
COTS	commercial off-the-shelf	IPv6	IP version 6
CP	control plane	IQ	in-phase and quadrature
CPRI	common public radio interface	ISG	industry specification group
CPS	configuration persistence service	KPI	key performance indicator
CPU	central processing unit	KPM	key performance measurement
CSI	communication service instance	L2	layer 2
CSMF	communication service management function	L3	layer 3
CST	communication service template	L3VPN	layer 3 VPN
CU	centralized unit	LF	linux foundation
D-RAN	distributed RAN	LTE	long term evolution
DARTs	disaggregated RAN transport study	M5G	MOSAIC 5G
DC	data center	M&O	management & orchestration
DCAE	data collection, analysis and event	MAC	medium access control
		MANO	management and orchestration
		MD	management domain
		MF	management function
		MH	midhaul
		ML	machine learning
		mMTC	massive machine type communication
		MNO	mobile network operator

MnS	management service	OTIC	open testing and integration center
MP	management plane	PDCP	packet data convergence protocol
MP-BGP	multi-protocol border gateway protocol	PE	provider edge
MPLS	multi-protocol label switching	PG	project group
MSCS	multi-site connectivity service	PHY	physical layer
MVP-C	minimum viable plan - committee	PLMN	public land mobile network
NB-IoT	narrowband IoT	PM	performance metric
Near-RT RIC	near-real-time RIC	PNF	physical network function
NF	network function	PoP	point-of-presence
nFAPI	network FAPI	PRB	physical resource block
NFL	network function layer	QoE	quality of experience
NFMF	network function management function	QoS	quality of service
NFMS_P	NFMS provider	RAM	random access memory
NFV	network function virtualization	RAN	radio access network
NFV-MANO	network functions virtualization management and orchestration	rApp	Non-RT RIC application
NFVI	NFV infrastructure	RAT	radio access technology
NFVO	network function virtualization orchestrator	RF	radio frequency
ng-eNB	next generation eNB	RIA	radio intelligence automation
NG-RAN	next-generation RAN	RIC	RAN intelligent controller
NIC	network interface card	RLC	radio link control
Non-RT RIC	non-real-time RIC	RoE	radio over ethernet
NR	new radio	ROMA	OpenRAN orchestration and management automation
NSaaS	network slice as a service	RRC	radio resource control
NSI	network slice instances	RRH	remote radio head
NSMF	network slice management function	RRM	radio resource management
NSSAI	network slice selection assistance information	RU	radio unit
NSSI	network slice subnet instance	S-NSSAI	single NSSAI
NSSMF	network slice subnet management function	S-RU	small cell RU
NSSMS_C	NSSMS consumer	SBA	services based architecture
NSSMS_P	NSSMS provider	SCF	small cell forum
NSST	network slice subnet template	SD	slice differentiator
NST	network slice template	SD-RAN	software-defined RAN
O-Cloud	O-RAN cloud platform	SDAP	service data adaptation protocol
O-CU	O-RAN CU	SDC	service design and creation
O-CU-CP	O-CU control plane	SDN	software-defined networking
O-CU-UP	O-CU user plane	SDN-C	SDN controller
O-DU	O-RAN DU	SDO	standards development organization
O-eNB	O-RAN eNB	SDR	software-defined radio
O-FH	open fronthaul	SID	segment ID
O-gNB	O-RAN gNodeB	SL	service layer
O-NSSI	O-RAN NSSI	SLA	service level agreement
O-RAN	Open RAN	SLE	service level expectation
O-RU	O-RAN RU	SMO	service management and orchestration
OAI	OpenAirInterface	SO	service orchestrator
OAM	operations and maintenance	SR	segment routing
ONAP	open network automation platform	SRS	software radio system
ONF	open networking foundation	SRv6	SR over IPv6
OOF	ONAP optimization framework	SST	slice/service type
OOM	ONAP operations manager	TCO	total cost of ownership
OPEX	operational expenditure	TDD	time division duplexing
OSA	OpenAirInterface software alliance	TE	traffic engineering
OSC	O-RAN software community	TIP	telecom infra project
OSM	open source MANO	TN	transport network
OSS	operations support system	TNE	transport network equipment
		TSC	technical steering committee

TSG	technical specification group
UE	user equipment
UMTS	universal mobile telecommunications system
UP	user plane
UPF	user plane function
URLLC	ultra reliable low latency communication
UI	use case user interface
V2X	vehicle to everything
VIM	virtualized infrastructure manager
VLAN	virtual LAN
VNF	virtualized network function
VNFM	virtual network functions manager
vO-CU	virtualize O-CU
vO-DU	virtualized O-DU
VPN	virtual private network
VPWS	virtual private wire service
WDM	wavelength division multiplexing
WG	working group
WIM	WAN infrastructure manager
xApp	Near-RT RIC application
ZSM	zero touch network and service management

ACKNOWLEDGMENT

This research was partially supported by the German Federal Ministry of Education and Research (BMBF) through the project 6G-Terafactory under Grant no. 16KISK186 and partially within the project Open6GHub under Grant no. 16KISK003K & 16KISK004. The authors are grateful to the anonymous reviewers for their insightful comments and valuable remarks, which have significantly improved the quality of this article.

KHURSHID ALAM received his B.Sc. degree in Computer and Communication Engineering from IUUC, Bangladesh, in 2008. He attained his M. Sc. degree in Applied Computer Science from the University of Kaiserslautern (RPTU) in 2018. Since then, he has been a researcher with the Intelligent Networks research group at the German Research Center for Artificial Intelligence GmbH (DFKI). From 2010 to 2012, he worked as a teaching assistant in Pokhara University, Nepal. From 2012 to 2015, he worked as an IT consultant for multiple

companies in Doha, Qatar. His research interests include industrial wireless communication, software defined networking, radio access network architecture, radio resource management, artificial intelligence, network function virtualization, and network slicing.

MOHAMMED ASIF HABIBI received his B.Sc. degree in Telecommunications Engineering from Kabul University, Afghanistan, in 2011. He obtained his M.Sc. degree in Systems Engineering and Informatics from the Czech University of Life Sciences, Czech Republic, in 2016. Since January 2017, he has been working as a research fellow and Ph.D. candidate at the Division of Wireless Communications and Radio Positioning, University of Kaiserslautern (RPTU), Germany. From 2011 to 2014, he worked as a radio access network engineer

for HUAWEI. His main research interests include network slicing, network function virtualization, resource allocation, machine learning, and radio access network architecture.

MATTHIAS TAMMEN received the M.Sc. degree in media and communication technology from the University of Kaiserslautern (RPTU) in 2019. Since then, he has been working as a Research Fellow at the Division of Wireless Communications and Radio Positioning (WiCoN), Department of Electrical Engineering (EIT), University of Kaiserslautern (RPTU). His main research interests include private campus networks, nomadic networks, media technology, and video transmission in 5G and beyond mobile communication networks.

DENNIS KRUMMACKER received the M.Sc. degree in Electrical and Computer Engineering from the University of Kaiserslautern (RPTU) in 2016. Since 2016, he has been a Researcher at the German Research Center for Artificial Intelligence GmbH (DFKI) in the Department of Intelligent Networks, where he is coordinating the research areas regarding Industrial Communication and Intelligent Infrastructures. His main research interests include Network Management and Orchestration, Softwarization, Virtualization, Software-defined Network (SDN), and

Network Function Virtualization (NFV).

WALID SAAD (Fellow, IEEE) received the Ph.D. degree from the University of Oslo, Norway, in 2010. He is currently a Professor with the Department of Electrical and Computer Engineering, Virginia Tech, where he leads the Network Science, Wireless, and Security Laboratory. He is also the Next-G Wireless Faculty Lead with Virginia Techs Innovation Campus. His research interests include wireless networks (5G/6G/beyond), machine learning, game theory, security, UAVs, semantic communications, cyberphysical systems, and network science. He is

also the recipient of the NSF CAREER Award in 2013, the AFOSR Summer Faculty Fellowship in 2014, and the Young Investigator Award from the Office of Naval Research in 2015. He was the (co)author of 11 conference best paper awards at IEEE WiOpt in 2009, ICIMP in 2010, IEEE WCNC in 2012, IEEE PIMRC in 2015, IEEE SmartGridComm in 2015, EuCNC in 2017, IEEE GLOBECOM in 2018 and 2020, IFIP NTMS in 2019, and IEEE ICC in 2020 and 2022. He is the recipient of the 2015 and 2022 Fred W. Ellersick Prize from the IEEE Communications Society, the IEEE Communications Society Marconi Prize Award in 2023, and the IEEE Communications Society Award for Advances in Communication in 2023. He was also a coauthor of the papers that received the IEEE Communications Society Young Author Best Paper Award in 2019, 2021, and 2023. Other recognitions include the 2017 IEEE ComSoc Best Young Professional in Academia Award, the 2018 IEEE ComSoc Radio Communications Committee Early Achievement Award, and the 2019 IEEE ComSoc Communication Theory Technical Committee Early Achievement Award. From 2015 to 2017, he was named the Stephen O. Lane Junior Faculty Fellow at Virginia Tech and, in 2017, he was named the College of Engineering Faculty Fellow. He received the Deans Award for Research Excellence from Virginia Tech in 2019. He has been annually listed in the Clarivate Web of Science Highly Cited Researcher List since 2019. He currently serves as an Area Editor for the IEEE Transactions on Network Science and Engineering and the IEEE Transactions on Communications. He is the Editor-in-Chief for the IEEE Transactions on Machine Learning in Communications and Networking. He was also an IEEE Distinguished Lecturer from 2019 to 2020.

MARCO DI RENZO (Fellow, IEEE) received the Laurea (cum laude) and Ph.D. degrees in electrical engineering from the University of L'Aquila, Italy, in 2003 and 2007, respectively, and the Habilitation Diriger des Recherches (Doctor of Science) degree from University Paris-Sud (currently Paris-Saclay University), France, in 2013. Currently, he is a CNRS Research Director (Professor) and the Head of the Intelligent Physical Communications group in the Laboratory of Signals and Systems (L2S) at Paris-Saclay University CNRS and CentraleSupélec,

Paris, France. Also, he is an elected member of the L2S Board Council and a member of the L2S Management Committee, and is a Member of the Admission and Evaluation Committee of the Ph.D. School on Information and Communication Technologies, Paris-Saclay University. He is a Founding Member and the Academic Vice Chair of the Industry Specification Group (ISG) on Reconfigurable Intelligent Surfaces (RIS) within the European Telecommunications Standards Institute (ETSI), where he served as the Rapporteur for the work item on communication models, channel models, and evaluation methodologies. He is a Fellow of the IEEE, IET, EURASIP, and AAIA; an Academician of AIIA; an Ordinary Member of the European Academy of Sciences and Arts, an Ordinary Member of the Academia Europaea; an Ambassador of the European Association on Antennas and Propagation; and a Highly Cited Researcher. Also, he holds the 2023 France-Nokia Chair of Excellence in ICT, he holds the Tan Chin Tuan Exchange Fellowship in Engineering at Nanyang Technological University (Singapore), and he was a Fulbright Fellow at City University of New York (USA), a Nokia Foundation Visiting Professor (Finland), and a Royal Academy of Engineering Distinguished Visiting Fellow (UK). His recent research awards include the 2021 EURASIP Best Paper Award, the 2022 IEEE COMSOC Outstanding Paper Award, the 2022 Michel Monpetit Prize conferred by the French Academy of Sciences, the 2023 EURASIP Best Paper Award, the 2023 IEEE ICC Best Paper Award, the 2023 IEEE COMSOC Fred W. Ellersick Prize, the 2023 IEEE COMSOC Heinrich Hertz Award, the 2023 IEEE VTS James Evans Avant Garde Award, and the 2023 IEEE COMSOC Technical Recognition Award from the Signal Processing and Computing for Communications Technical Committee. He served as the Editor-in-Chief of IEEE Communications Letters during the period 2019-2023, and he is now serving in the Advisory Board. He is currently serving as a Voting Member of the Fellow Evaluation Standing Committee and as the Director of Journals of the IEEE Communications Society.

TOMMASO MELODIA (Fellow, IEEE) received the Ph.D. degree in electrical and computer engineering from the Georgia Institute of Technology in 2007. He is the William Lincoln Smith Chair Professor with the Department of Electrical and Computer Engineering, Northeastern University, Boston. His research on modeling, optimization, and experimental evaluation of Internet of Things and wireless networked systems has been funded by the National Science Foundation, the Air Force Research Laboratory, the Office of Naval Research, DARPA, and the

Army Research Laboratory. He is also the Founding Director of the Institute for the Wireless Internet of Things and the Director of Research for the PAWR Project Office. He is a recipient of the National Science Foundation CAREER Award. He has served as an Associate Editor for IEEE Transactions on Wireless Communications, IEEE Transactions on Mobile Computing, and Computer Networks (Elsevier). He has served as the Technical Program Committee Chair for IEEE Infocom 2018, and the General Chair for IEEE SECON 2019, ACM Nanocom 2019, and ACM WUWnet 2014. He is the Director of Research for the Platforms for Advanced Wireless Research (PAWR) Project Office, a \$100M publicprivate partnership to establish 4 city-scale platforms for wireless research to advance the U.S. wireless ecosystem in years to come. He is a Distinguished Member of the ACM.

XAVIER COSTA-PÉREZ (M'06–SM'18) is Head of 6G Networks R&D at NEC Laboratories Europe, Scientific Director at the i2Cat R&D Center, and Research Professor at ICREA. His team contributes to products roadmap evolution as well as to European Commission R&D collaborative projects and received several awards for successful technology transfers. In addition, the team contributes to related standardization bodies: 3GPP, ETSI NFV, ETSI MEC, and IETF. Xavier has been a 5GPPP Technology Board member, served on the Program

Committee of several conferences (including IEEE Greencom, WCNC, and INFOCOM), published at top research venues, and holds several patents. He also serves as Editor of IEEE Transactions on Mobile Computing and Transactions on Communications journals. He received both his M.Sc. and Ph.D. degrees in Telecommunications from the Polytechnic University of Catalonia (UPC) in Barcelona and was the recipient of a national award for his Ph.D. thesis.

MÉROUANE DEBBAH (Fellow, IEEE) is Professor at Khalifa University of Science and Technology in Abu Dhabi. He received the M.Sc. and Ph.D. degrees from the Ecole Normale Supérieure Paris-Saclay, France. He was with Motorola Labs, Saclay, France, from 1999 to 2002, and then with the Vienna Research Center for Telecommunications, Vienna, Austria, until 2003. From 2003 to 2007, he was an Assistant Professor with the Mobile Communications Department, Institut Eurecom, Sophia Antipolis, France. Since 2007, he is Full Professor

at CentraleSupélec, Gif-sur-Yvette, France. From 2007 to 2014, he was the Director of the Alcatel-Lucent Chair on Flexible Radio. From 2014 to 2021, he was Vice-President of the Huawei France Research Center. He was jointly the director of the Mathematical and Algorithmic Sciences Lab as well as the director of the Lagrange Mathematical and Computing Research Center. From 2021 to 2023, he was Chief Researcher at the Technology Innovation Institute and leading the AI & Digital Science Research centers at the Technology Innovation Institute. He was also Adjunct Professor with the Department of Machine Learning at the Mohamed Bin Zayed University of Artificial Intelligence in Abu Dhabi. Since 2023, he is Professor at at Khalifa University of Science and Technology in Abu Dhabi and founding director of the 6G center. He has managed 8 EU projects and more than 24 national and international projects. His research interests lie in fundamental mathematics, algorithms, statistics, information, and communication sciences research. He holds more than 40 patents. He is an IEEE Fellow, a WWRF Fellow, a Eurasip Fellow, an AAIA Fellow, an Institut Louis Bachelier Fellow and a Membre mrite SEE. He was a recipient of the ERC Grant MORE (Advanced Mathematical Tools for Complex Network Engineering) from 2012 to 2017. He was a recipient of the Mario Boella Award in 2005, the IEEE Glavieux Prize Award in 2011, the Qualcomm Innovation Prize Award in 2012, the 2019 IEEE Radio Communications Committee Technical Recognition Award and the 2020 SEE Blondel Medal. He received more than 30 best paper awards, among which the 2007 IEEE GLOBECOM Best Paper Award, the Wi-Opt 2009 Best Paper Award, the 2010 Newcom++ Best Paper Award, the WUN CogCom Best Paper 2012 and 2013 Award, the 2014 WCNC Best Paper Award, the 2015 ICC Best Paper Award, the 2015 IEEE Communications Society Leonard G. Abraham Prize, the 2015 IEEE Communications Society Fred W. Ellersick Prize, the 2016 IEEE Communications Society Best Tutorial Paper Award, the 2016 European Wireless Best Paper Award, the 2017 Eurasp Best Paper Award, the 2018 IEEE Marconi Prize Paper Award, the 2019 IEEE Communications Society Young Author Best Paper Award, the 2021 Eurasp Best Paper Award, the 2021 IEEE Marconi Prize Paper Award, the 2022 IEEE Communications Society Outstanding Paper Award, the 2022 ICC best paper Award, the 2022 IEEE GLOBECOM Best Paper Award, 2022 IEEE TAOS TC Best GCSN Paper Award, the 2022 IEEE International Conference on Metaverse Best Paper Award, the 2023 IEEE Communications Society Fred W. Ellersick Prize, the 2023 ICC best paper award as well as the Valuetools 2007, Valuetools 2008, CrownCom 2009, Valuetools 2012, SAM 2014, and 2017 IEEE Sweden VT-COM-IT Joint Chapter best student paper awards. He is an Associate Editor-in-Chief of the journal Random Matrix: Theory and Applications. He was an Associate Area Editor and Senior Area Editor of the IEEE TRANSACTIONS ON SIGNAL PROCESSING from 2011 to 2013 and from 2013 to 2014, respectively. From 2021 to 2022, he served as an IEEE Signal Processing Society Distinguished Industry Speaker.

ASHUTOSH DUTTA (Fellow, IEEE) is currently Chief 5G Strategist and JHU/APL Sabbatical Fellow at Johns Hopkins University Applied Physics Labs (JHU/APL), USA. He also serves as Chair for Electrical and Computer Engineering for Engineering Professional Program at JHU. His career, spanning more than 30 years, includes Director of Technology Security and Lead Member of Technical Staff at AT&T, CTO of Wireless at a Cybersecurity company NIKSUN, Inc., Senior Scientist in Telcordia Research, Director of Central Research Facility at

Columbia University, adjunct faculty at NJIT, and Computer Engineer with TATA Motors. Ashutosh is author of more than 100 technical papers and 31 issued patents. Ashutosh is co-author of the book, titled, Mobility Protocols and Handover Optimization: Design, Evaluation and Application published by IEEE and John & Wiley. As a Technical Leader in 5G and security, Ashutosh has been serving as the founding Co-Chair for the IEEE Future Networks Initiative that focuses on 5G standardization, education, publications, testbed, and roadmap activities. Ashutosh is IEEE Communications Society's Distinguished Lecturer for 2017-2020 and as an ACM Distinguished Speaker (2020-2022). Ashutosh currently serves as the founding co-chair for IEEE Future Networks Initiative and Member-At-Large for IEEE Communications Society. He co-founded the IEEE STEM conference (ISEC) and helped to implement EPICS (Engineering Projects in Community Service) projects in several high schools. Ashutosh has served as the general Co-Chair for the IEEE STEM conference for the last 10 years. Ashutosh served as the Director of Industry Outreach for IEEE Communications Society from 2014-2019. He was recipient of 2009 IEEE MGA Leadership award. Ashutosh is recipient of IEEE-USAs 2010 Professional Leadership Award, 2022 IEEE-USA George F. McClure Citation of Honor. He also received 2022 IEEE North American Region Exceptional Service Award. Ashutosh served as Member-At-Large for IEEE Communications Society for 2020-2022. Ashutosh has served as the founding Co-Chair for the premier IEEE 5G World Forums and has organized 85 5G World Summits around the world. Ashutosh currently serves as the Chair for IEEE Industry Connections O-RAN activities and IPv6. Ashutosh is a Distinguished Alumnus of NIT Rourkela with BS in Electrical Engineering, MS in Computer Science from NJIT, and Ph.D. in Electrical Engineering from Columbia University under the supervision of Prof. Henning Schulzrinne. Ashutosh is a Fellow of IEEE and Distinguished member ACM.

HANS D. SCHOTTEN (S'93-M'97) received the Ph.D. degree from the RWTH Aachen University of Technology, Germany, in 1997. From 1999 to 2003, he worked for Ericsson. From 2003 to 2007, he worked for Qualcomm. He became manager of a R&D group, Research Coordinator for Qualcomm Europe, and Director for Technical Standards. In 2007, he accepted the offer to become a full professor at the University of Kaiserslautern (RPTU). In 2012, he - in addition - became the scientific director of the German Research Center for Artificial

Intelligence (DFKI) and head of the Department for Intelligent Networks. Professor Schotten served as dean of the Department of Electrical Engineering of the Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau from 2013 until 2017. Since 2018, he is chairman of the German Society for Information Technology and a member of the Supervisory Board of the VDE. He is the author of more than 200 papers and participated in 30+ European and national collaborative research projects.
