# On the K-theory of $\mathbf{Z} / p^{n}$ 

Benjamin Antieau, Achim Krause, Thomas Nikolaus

May 8, 2024

#### Abstract

We give an explicit algebraic description, based on prismatic cohomology, of the algebraic K-groups of rings of the form $\mathcal{O}_{K} / \mathfrak{I}$ where $K$ is a $p$-adic field and $\mathfrak{I}$ is a non-trivial ideal in the ring of integers $\mathcal{O}_{K}$; this class includes the rings $\mathbf{Z} / p^{n}$ where $p$ is a prime.

The algebraic description allows us to describe a practical algorithm to compute individual K-groups as well as to obtain several theoretical results: the vanishing of the even K-groups in high degrees, the determination of the orders of the odd K-groups in high degrees, and the degree of nilpotence of $v_{1}$ acting on the $\bmod p$ syntomic cohomology of $\mathbf{Z} / p^{n}$.

## 1 Introduction

We fix the following notation for the entire paper. Let $\mathcal{O}_{K}$ be a complete discrete valuation ring with finite residue field $k=\mathbf{F}_{q}$ and quotient field $K$ of characteristic zero, which is necessarily finite over $\mathbf{Q}_{p}$ of some degree $d$. Let $q=p^{f}$, where $f$ is the residual degree. One has $d=f e$ for some positive integer $e$ called the ramification index. Fix a choice of a uniformizer $\varpi \in \mathcal{O}_{K} ; e$ is the unique integer such that the ideals $(p)$ and $\left(\varpi^{e}\right)$ are equal in $\mathcal{O}_{K}$.

The fields $K$ that arise this way are the $p$-adic number fields; rings of integers such as $\mathcal{O}_{K}$ are $p$-adic number rings. The quotients $\mathcal{O}_{K} / \varpi^{n}$ are called finite chain rings [15].

### 1.1 Results

The problem of computing the K-groups of the quotient rings $\mathcal{O}_{K} / \varpi^{n}$ was raised by Swan in 1972; see [23, Prob. 20]. When $n=1$, we have $\mathcal{O}_{K} / \varpi=\mathbf{F}_{q}$; the K-groups of finite fields were computed by Quillen in [37] (see also [28]):

$$
\mathrm{K}_{r}\left(\mathbf{F}_{q}\right) \cong \begin{cases}\mathbf{Z} & \text { if } r=0  \tag{1}\\ \mathbf{Z} /\left(q^{i}-1\right) & \text { if } r=2 i-1, \text { and } \\ 0 & \text { otherwise }\end{cases}
$$

Since $p$ does not divide $q^{i}-1$, letting $\mathrm{K}\left(-; \mathbf{Z}\left[\frac{1}{p}\right]\right)$ denote the prime-to- $p$ localization of algebraic K-theory, we have $\mathrm{K}_{r}\left(\mathbf{F}_{q}\right) \cong \mathrm{K}_{r}\left(\mathbf{F}_{q} ; \mathbf{Z}\left[\frac{1}{p}\right]\right)$ for $r \geqslant 1$, while $\mathrm{K}\left(\mathbf{F}_{q} ; \mathbf{Z}_{p}\right) \simeq \mathbf{Z}_{p}$, where $\mathrm{K}\left(-; \mathbf{Z}_{p}\right)$ denotes the $p$-adic completion. When $n \leqslant e, \mathcal{O}_{K} / \varpi^{n} \cong \mathbf{F}_{q}[z] / z^{n}$. The K-groups of truncated polynomial rings over finite fields were completely described by Hesselholt and Madsen in [25] (see also [41, 42]). These are the only cases where a complete computation is known.

The K-groups $\mathrm{K}_{r}\left(\mathcal{O}_{K} / \varpi^{n}\right)$ of $\mathcal{O}_{K} / \varpi^{n}$ are finitely generated abelian groups, torsion for $r \geqslant 1$, and their prime-to- $p$ information is determined by Quillen's computation of the K-groups of finite fields: $\mathrm{K}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}\left[\frac{1}{p}\right]\right) \simeq$ $\mathrm{K}\left(\mathbf{F}_{q} ; \mathbf{Z}\left[\frac{1}{p}\right]\right)$, as can be proved by using group homology techniques. It remains to compute the $p$-complete K-groups $\mathrm{K}_{r}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right)$. For $r \geqslant 0, \mathrm{~K}_{r}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right) \cong \mathrm{TC}_{r}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right)$ by the Dundas-GoodwillieMcCarthy theorem (see Corollary 2.5).

Bhatt, Morrow, and Scholze introduced in [10] p-adic syntomic complexes $\mathbf{Z}_{p}(i)(R)$ for quasisyntomic rings $R$; these are objects in the $p$-complete derived category $\mathrm{D}\left(\mathbf{Z}_{p}\right)_{p}^{\wedge}$. They gave a complete decreasing filtration $\mathrm{F}_{\text {mot }}^{\geqslant \star} \mathrm{TC}\left(R ; \mathbf{Z}_{p}\right)$ with graded pieces $\operatorname{gr}_{\text {mot }}^{i} \mathrm{TC}\left(R ; \mathbf{Z}_{p}\right) \simeq \mathbf{Z}_{p}(i)(R)[2 i]$. The associated spectral sequence then converges from the cohomology of these complexes to the homotopy groups of $\mathrm{TC}\left(R ; \mathbf{Z}_{p}\right)$. We will show
that in the case of $\mathcal{O}_{K} / \varpi^{n}$, the spectral sequence collapses for degree reasons and that there are no possible extensions (see Corollary 2.16). As $\mathrm{H}^{0}\left(\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)\right)=0$ for $i \geqslant 1$ (Corollary 2.14), we conclude that

$$
\mathrm{K}_{2 i-1}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right) \cong \mathrm{H}^{1}\left(\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)\right)
$$

for $i \geqslant 1$ and

$$
\mathrm{K}_{2 i-2}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right) \cong \mathrm{H}^{2}\left(\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)\right)
$$

for $i \geqslant 2, \mathrm{~K}_{0}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right) \cong \mathrm{H}^{0}\left(\mathbf{Z}_{p}(0)\left(\mathcal{O}_{K} / \varpi^{n}\right)\right) \cong \mathbf{Z}_{p}$.
This paper has three main results. The first gives a practical algorithm for computing the $p$-adic syntomic complexes $\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)$.

Theorem 1.1. Given $K, n, i \geqslant 1$, and a fixed uniformizer $\varpi \in \mathcal{O}_{K}$, there is an explicit, algorithmically computable three-term cochain complex

$$
\begin{equation*}
\cdots \rightarrow 0 \rightarrow \mathbf{Z}_{p}^{f(i n-1)} \xrightarrow{\operatorname{syn}^{0}} \mathbf{Z}_{p}^{2 f(i n-1)} \xrightarrow{\text { syn }^{1}} \mathbf{Z}_{p}^{f(i n-1)} \rightarrow 0 \rightarrow \cdots \tag{2}
\end{equation*}
$$

concentrated in cohomological degrees $0,1,2$ of finite rank free $\mathbf{Z}_{p}$-modules which is is quasi-isomorphic to $\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)$.

Our approach relies on a detailed examination of prismatic envelopes and is heavily influenced by the work of Liu-Wang [33] who introduced a topological version of the local-to-global descent arguments given below to recover the calculation of $\mathrm{K}\left(\mathcal{O}_{K} ; \mathbf{F}_{p}\right)$ of Hesselholt-Madsen [27].

Remark 1.2. The differentials $\operatorname{syn}^{0}$ and $\operatorname{syn}^{1}$ are $p$-adic matrices; the algorithm is to construct these matrices up to sufficient $p$-adic precision. As mentioned above, the map syn ${ }^{0}$ is injective by Corollary 2.14 so that this cochain complex has cohomology only in degrees 1 and 2 .

Remark 1.3. The computability of these groups is not new and follows also from a combination of homological stability (see $[43,46]$ ) and the fact that homotopy groups of finite CW complexes with finite homotopy groups are computable, for example via minimal Kan complexes or by Serre's fibration method. See [12] for the classical approach and [40] for a more modern survey which also presents Kenzo, a computer package for making such computations. In [17], a SAGE interface for Kenzo is described. In practice, these approaches are feasible only in very low degrees. The novelty in our approach is the reduction to linear algebra using prismatic cohomology which also allows us to compute high-degree K-groups independently of low-degree groups.

In particular, writing $\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)^{\bullet}$ for our explicit cochain complex model for $\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)$, we have for $i \geqslant 1$ that

$$
\begin{aligned}
& \mathrm{H}^{0}\left(\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)^{\bullet}\right)=0 \\
& \mathrm{H}^{1}\left(\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)^{\bullet}\right) \cong \mathrm{K}_{2 i-1}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right) \\
& \mathrm{H}^{2}\left(\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)^{\bullet}\right) \cong \mathrm{K}_{2 i-2}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right) \quad(\text { if additionally } i \geqslant 2)
\end{aligned}
$$

These groups can thus be computed using elementary divisors from the matrices syn ${ }^{0}$ and $\operatorname{syn}^{1}$.
We have implemented in [5] the computation of the matrices $\operatorname{syn}^{0}$ and $\operatorname{syn}^{1}$ in SAGE 10.2 [44] in the special case where $f=1$, so that the residue field is $\mathbf{F}_{p}$. For example, Figure 1 displays a table of K-groups for some small rings we obtained through computer algebra computations. Similar computations can be carried out for many more examples and degrees and we present extended calculations in Appendix A.

In addition to computational results in small degrees, our approach allows us to deduce some abstract statements about $\mathrm{K}_{*}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right)$. A striking pattern in Figure 1 is that the K-groups seem to vanish in even degrees from some point.

Our second theorem is that this is always true, which we prove by showing that the differential syn ${ }^{1}$ from (2) is surjective for $i$ sufficiently large.

|  | $\mathbf{F}_{2}$ | Z/4 | Z/8 | $\mathbf{F}_{2}[z] / z^{3}$ |

| $\mathrm{K}_{10}$ | 0 | 0 | 0 | 0 |

Figure 1: Low-degree K-groups of some small rings. The gray terms were known prior to this paper.

Theorem 1.4 (The even vanishing theorem). If

$$
i-1 \geqslant \frac{p}{p-1}\left(\frac{p}{p-1}\left(p^{\left\lceil\frac{n}{e}\right\rceil}-1\right)-p^{\left\lceil\frac{n}{e}\right\rceil}\left(\left\lceil\frac{n}{e}\right\rceil-\frac{n}{e}\right)\right)
$$

(and $i \geqslant 2$ ), then $K_{2 i-2}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right)=0$ for all $p$-adic fields $K$ of ramification index $e .^{1}$
Another result we extract from our methods is the following proposition, in which we use $|A|$ to denote the order of a finite abelian group $A$. It was stated and proved by Angeltveit [2] in the unramified case, i.e., for rings of the form $W\left(\mathbf{F}_{q}\right) / p^{n}$.

Proposition 1.5 (Angeltveit's quotient). For any $p$-adic number field $K$ and any $n \geqslant 1$ and $i \geqslant 2$,

$$
\frac{\left|\mathrm{K}_{2 i-1}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right)\right|}{\left|\mathrm{K}_{2 i-2}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right)\right|}=q^{i(n-1)}
$$

Together, the even vanishing theorem and Angeltveit's quotient imply the following corollary.
Corollary 1.6. For $i \gg 0, \mathrm{~K}_{2 i-1}\left(\mathcal{O}_{K} / \varpi^{n}\right)$ has order $\left(q^{i}-1\right) q^{i(n-1)}$.
A nice way to summarize these results is that, in large degrees, the orders of $\mathrm{K}_{*}\left(\mathcal{O}_{K} / \varpi^{n}\right)$ and $\mathrm{K}_{*}\left(\mathbf{F}_{q}[z] / z^{n}\right)$ agree, even though the groups might differ.

For a fixed ring $\mathcal{O}_{K} / \varpi^{n}$, by applying Theorem 1.1 in low degrees and Corollary 1.6 in high degrees, one reduces the determination of the orders of all K-groups of $\mathcal{O}_{K} / \varpi^{n}$ to a finite number of applications of the algorithm.

Example 1.7. For $\mathbf{Z} / 4$, Theorem 1.4 and the values from the table in Appendix A. 1 show that the only positive degree non-zero even K-group is $K_{2}(\mathbf{Z} / 4) \cong \mathbf{Z} / 2$. It follows that the orders of the K-groups of $\mathbf{Z} / 4$ are

$$
\left|\mathrm{K}_{r}(\mathbf{Z} / 4)\right| \cong \begin{cases}2 & \text { if } r=1,2 \\ 24 & \text { if } r=3 \\ \left(2^{i}-1\right) 2^{i} & \text { if } r=2 i-1 \text { for } i \geqslant 3 \\ 0 & \text { otherwise }\end{cases}
$$

for $r \geqslant 1$.
Another application of our results is to reprove the main step in the proof of the theorem of Bhatt-Clausen-Mathew [7] (reproved and generalized by Land-Mathew-Meier-Tamme [31]), which says that $\mathrm{L}_{T(1)} \mathrm{K}(R) \simeq \mathrm{L}_{T(1)} \mathrm{K}\left(R\left[\frac{1}{p}\right]\right)$, where $\mathrm{L}_{T(1)}$ denotes the height 1 telescopic localization at the prime $p$. The main step is to prove that

$$
\mathrm{L}_{T(1)} \mathrm{K}\left(\mathbf{Z} / p^{n}\right) \simeq 0
$$

[^0]for all $n \geqslant 1$. For $n=1$, this follows from Quillen's computation (1). For $n \geqslant 2$, other arguments are needed. In [7], the argument goes by reduction to the case of $\mathcal{O}_{\mathbf{C}_{p}} / p^{n}$ and an argument using prismatic cohomology and prismatic envelopes; in [31], the argument uses excision results.

Our third theorem is a finer vanishing result, giving a bound on the degree of $v_{1}$-nilpotence of $\mathrm{K}\left(\mathbf{Z} / p^{n} ; \mathbf{F}_{p}\right)$. See Section 6.

Theorem 1.8. The class $v_{1} \in \mathbf{F}_{p}(p-1)\left(\mathbf{Z} / p^{n}\right)$ has nilpotence degree exactly $[n]_{p}=\frac{p^{n}-1}{p-1}$ in the motivic associated graded

$$
\operatorname{gr}_{\mathrm{mot}}^{\star} \mathrm{TC}\left(\mathbf{Z} / p^{n} ; \mathbf{F}_{p}\right) \simeq \bigoplus_{i \geqslant 0} \mathbf{F}_{p}(i)\left(\mathbf{Z} / p^{n}\right)
$$

Remark 1.9. It follows that for primes $p \geqslant 5$, the self map $v_{1}$ of $\mathrm{K}\left(\mathbf{Z} / p^{n} ; \mathbf{F}_{p}\right)$ has nilpotence degree between $[n]_{p}$ and $2[n]_{p}$ using that in these cases $\mathrm{K}\left(\mathbf{Z} / p^{n} ; \mathbf{F}_{p}\right)$ is a homotopy associative ring spectrum; see Corollary 6.5. However, the work of Hahn-Levy-Senger (see Remark 1.11) can be used to show that it has nilpotency degree either $[n]_{p}$ or $[n]_{p}+1$.

Remark 1.10. There is a version of Theorem 1.8 for ramified extensions as well. In that case, one has that $v_{1}$ has nilpotence degree at most

$$
\frac{p^{\left\lceil\frac{n}{e}\right\rceil}-1}{p-1}
$$

when acting on the motivic associated graded. This bound is sharp when $e$ divides $n$. See Theorem 6.3.

### 1.2 History

Kuku proved that if $R$ is a finite associative ring, then $\mathrm{K}_{r}(R)$ is a finite abelian group for $r>0$; see [47, Prop. IV.1.16].

Work of Dennis and Stein [19] treats $\mathrm{K}_{2}\left(\mathcal{O} / \varpi^{n}\right)$. This is the only previous paper we know which considers the higher algebraic K-theory of general rings of this form.

As mentioned above, the K-groups of the characteristic $p$ quotients $\mathbf{F}_{q}[z] / z^{n}$ (so, when $n \leqslant e$ ) were described by Hesselholt-Madsen [25]. Their calculations have been revisited by Speirs [41], Mathew [35], and Sulyma [42] using modern advances in cyclotomic spectra and prismatic cohomology. (They have also been generalized to truncated polynomial rings over perfectoid rings by Riggenbach [39].)

The K-groups in the unramified case have been considered by many researchers. Evens and Friedlander [21] computed $\mathrm{K}_{3}\left(\mathbf{Z} / p^{2}\right)$ and $\mathrm{K}_{4}\left(\mathbf{Z} / p^{2}\right)$ for $p \geqslant 5$ and Aisbett, Lluis-Puebla, and Snaith [1] worked on $\mathrm{K}_{3}\left(\mathbf{Z} / p^{n}\right)$ and $\mathrm{K}_{3}\left(\mathbf{F}_{q}[z] / z^{2}\right)$. Geisser computed $\mathrm{K}_{3}\left(W\left(\mathbf{F}_{q}\right) / p^{2}\right)$ for $p \geqslant 3$, correcting a mistake in Aisbett et al. at $p=3$.

Brun [14] computed $\mathrm{K}_{r}\left(\mathbf{Z} / p^{n}\right)$ for $r \leqslant p-3$ and Angeltveit [2] computed $\mathrm{K}_{r}\left(W\left(\mathbf{F}_{q}\right) / p^{n}\right)$ for $r \leqslant 2 p-2$, but his results in conjunction with Proposition 1.5 also give the order of $\mathrm{K}_{2 p-1}\left(W\left(\mathbf{F}_{q}\right) / p^{n}\right)$. One consequence of Angeltveit's calculation is the discovery of an error in the calculation of $K_{3}(\mathbf{Z} / 4)$ in Aisbett et al.; Angeltveit's calculation gives the correct order and the correct group structure is given by our calculations in Figure 1. We thank Markus Szymik for bringing this to our attention.

In the limit, the $p$-adic K-theory of $\mathcal{O}_{K}$ itself was an important test case for the Quillen-Lichtenbaum conjecture and was computed by Hesselholt and Madsen [27]. This calculation was revisited by Liu and Wang [33] with $\mathbf{F}_{p}$-coefficients.

Our approach is very similar to that of Liu and Wang [33] and also to the method used in [30] for computing THH of $\mathcal{O}_{K}$ and $\mathcal{O}_{K} / \varpi^{n}$; indeed, what we do can be viewed as a purely prismatic analogue of the topological story in [30, 33].

Remark 1.11. Hahn, Levy, and Senger have recently announced a complete calculation of $\mathrm{K}\left(\mathbf{Z} / p^{n}\right) /\left(p, v_{1}\right)$ for odd primes; the resulting groups are independent of $n$, for $n \geqslant 2$.

Organization. Section 2 gives an overview of our approach to the calculation of $\mathrm{K}_{*}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right)$. Section 3 contains a detailed analysis of the algebra of prismatic envelopes and Section 4 gives our approach to explicit relative-to-absolute descent. Section 5 gives the proof of the even vanishing theorem and Section 6 gives the proof of the $v_{1}$-nilpotence theorem. Finally, Section 7 details the algorithm for computing the K-groups.

Acknowledgments. We are very grateful to Bhargav Bhatt, Dustin Clausen, Thomas Geisser, Jeremy Hahn, Lars Hesselholt, Ishan Levy, Akhil Mathew, Noah Riggenbach, Peter Scholze, Andrew Senger, Markus Szymik, and Chuck Weibel for comments on [3] and the results in this paper. Additionally, Yuanning Zhang and Jeremy Hahn each pointed out a typo in one of the tables in [3].

BA was supported by NSF grants DMS-2120005, DMS-2102010, and DMS-2152235, by Simons Fellowship 666565 , and by the Simons Collaboration on Perfection; he would like to thank Universität Münster for its hospitality during a visit in 2020. AK and TN were funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) - Project-ID 427320536 - SFB 1442, as well as under Germany's Excellence Strategy EXC 2044 390685587, Mathematics Münster: Dynamics-Geometry-Structure. They would also like to thank the Mittag-Leffler Institute for its hospitality while working on this project.

This paper also benefited from the opportunity for BA and AK to give a masterclass on the topic in Copenhagen in early 2023. We thank the organizers (Shachar Carmeli, Lars Hesselholt, Ryomei Iwasa, and Mikala Jansen) and the Copenhagen Centre for Geometry and Topology for the opportunity.

Finally, BA and AK thank the Institute for Advanced Study for its hospitality in early 2024 when we finished this paper. BA was supported there by NSF grant DMS-1926686. AK was supported by a grant from the Institute of Advanced Study School of Mathematics.

The tables in Appendix A were created under allocation p31679 using QUEST, a high-performance cluster at Northwestern University.

## 2 Strategy

In this section, we give the theoretical results which reduce the computation of the K-groups of $\mathcal{O}_{K} / \varpi^{n}$ to a finite computation involving prismatic cohomology. We will make heavy use of prismatic cohomology relative to $\delta$-rings and its filtered variant, for which we refer to our companion paper [4]. In general, let $\triangle_{R / A}$ denote the prismatic package of a $\delta$-pair, possibly filtered, from which we can functorially extract relative syntomic complexes $\mathbf{Z}_{p}(i)(R / A)$, which are equipped with natural filtrations for filtered $\delta$-pairs. We are most interested in the case when $A=\mathbf{Z}_{p}$ or $W(k)$ with the trivial filtration, in which case we will write $\triangle_{R}$ and $\mathbf{Z}_{p}(i)(R)$ for the absolute theories. The prismatic cohomology package contains the data of prismatic cohomology, the Hodge-Tate tower, Breuil-Kisin twists, and Nygaard-filtered Nygaard-completed Frobenius-twisted prismatic cohomology, together with canonical and Frobenius maps.

### 2.1 General reductions

To begin with, the groups we are interested in are finitely generated abelian groups, making an algorithmic approach feasible. Weibel [47] attributes the group homology proof of this fact to Aderemi Kuku.

Proposition 2.1 (Kuku). If $A$ is a finite associative ring, then for each $r \geqslant 1$ the K -group $\mathrm{K}_{r}(A)$ is finitely generated and torsion.

Corollary 2.2. For each $r \geqslant 1$, the K -group $\mathrm{K}_{r}\left(\mathcal{O}_{K} / \varpi^{n}\right)$ is finitely generated and torsion.
As above, let $\mathbf{Z}\left[\frac{1}{p}\right]$ denote the prime-to- $p$ localization of $\mathbf{Z}$. We let $\mathrm{K}\left(-; \mathbf{Z}\left[\frac{1}{p}\right]\right)$ be the prime-to- $p$ localization of $\mathrm{K}(-)$, and similarly for other functors.

Corollary 2.3. The natural map $\mathrm{K}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}\left[\frac{1}{p}\right]\right) \rightarrow \mathrm{K}\left(\mathbf{F}_{q} ; \mathbf{Z}\left[\frac{1}{p}\right]\right)$ is an equivalence.
Proof. This follows from the fact that the kernel of the surjective homomorphism $\mathbf{G L}\left(\mathcal{O}_{K} / \varpi^{n}\right) \rightarrow \mathbf{G L}\left(\mathbf{F}_{q}\right)$ is a $p$-group.

The result we need for $p$-adic K-theory is the Dundas-Goodwillie-McCarthy theorem; see also the rigidity result of Clausen-Mathew-Morrow [16].

Theorem 2.4 (Dundas-Goodwillie-McCarthy [20]). If $A$ is an associative ring and $I$ is a 2-sided nilpotent ideal in $A$, then the natural commutative square

is a pullback square.
In the theorem, note that if $A$ is $p$-nilpotent, then $\mathrm{TC}(A)$ and $\mathrm{TC}(A / I)$ are $p$-complete.
Corollary 2.5. The natural map $\mathrm{K}_{r}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right) \rightarrow \mathrm{TC}_{r}\left(\mathcal{O}_{K} / \varpi^{n}\right)$ is an isomorphism for $r \geqslant 0$.
Proof. This follows from Theorem 2.4 and the fact that $\mathrm{K}\left(\mathbf{F}_{q} ; \mathbf{Z}_{p}\right) \rightarrow \mathrm{TC}\left(\mathbf{F}_{q}\right)$ is $(-2)$-truncated by Quillen's computation of the K-theory of finite fields and the calculation of Hesselholt-Madsen [26, Thm. B] of TC of perfect fields of characteristic $p$; see also [36, Cor. IV.4.10].

In order to compute the TC-groups of $\mathcal{O}_{K} / \varpi^{n}$, and hence the higher $p$-adic K-groups, we use the theory of syntomic cohomology first defined in [10] (see also [22, 29] and [6] for a comparison). This gives, for a quasisyntomic ring $R$ a sequence of $p$-complete complexes $\mathbf{Z}_{p}(i)(R)$ in the $p$-complete derived category $\mathrm{D}\left(\mathbf{Z}_{p}\right)_{p}^{\wedge}$ and a complete multiplicative decreasing filtration $\mathrm{F}_{\text {mot }}^{\geqslant \star} \mathrm{TC}\left(R ; \mathbf{Z}_{p}\right)$ with graded pieces

$$
\operatorname{gr}_{\mathrm{mot}}^{i} \mathrm{TC}\left(R ; \mathbf{Z}_{p}\right) \simeq \mathbf{Z}_{p}(i)(R)[2 i] .
$$

The associated spectral sequence takes the form

$$
\mathrm{E}_{2}^{i, j}=\mathrm{H}^{i-j}\left(\mathbf{Z}_{p}(-j)(R)\right) \Rightarrow \mathrm{TC}_{-i-j}\left(R ; \mathbf{Z}_{p}\right)
$$

with differentials $d_{r}$ of bidegree $(r, 1-r)$. The goal in this paper is to compute the cohomology of the complexes $\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)$. It turns out that in this case the motivic filtration on $\mathrm{TC}\left(R ; \mathbf{Z}_{p}\right)$ is simple enough that there is no additional work needed to go from the cohomology of the $\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)$ to the $p$-adic K-groups: the associated spectral sequence degenerates and there are no non-trivial extensions for degree reasons. See Corollary 2.16.

### 2.2 Prismatic and syntomic cohomology

By the definition in [10], for $i \in \mathbf{Z}$, the $i$ th syntomic complex of a quasisyntomic ring $R$ is

$$
\mathbf{Z}_{p}(i)(R)=\mathrm{fib}\left(\mathrm{~N}^{\geqslant i} \widehat{\triangle}_{R}\{i\} \xrightarrow{\text { can }-\varphi} \widehat{\mathbb{}}_{R}\{i\}\right)
$$

in $\mathrm{D}\left(\mathbf{Z}_{p}\right)_{p}^{\wedge}$, where $\widehat{\triangle}_{R}\{i\}$ is the $i$ th Breuil-Kisin twisted Nygaard-complete absolute prismatic cohomology of $R$ and $\mathrm{N} \geqslant i \widehat{\triangle}_{R}\{i\}$ is the $i$ th stage of the Nygaard filtration.

Our goal in this section is to bound the complexity of $\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)$, which we do by comparison with the characteristic $p$ case via a philosophy we will refer to as crystalline degeneration. Indeed, the rings $\mathcal{O}_{K} / \varpi^{n}$ are filtered by $\varpi$-adic powers. The associated graded ring is $\mathbf{F}_{q}[z] / z^{n}$, which we view as being $z$-adically filtered. These filtrations induce secondary filtrations on all of the invariants in the picture: prismatic cohomology, THH, TC, etc. We will in all cases write $\mathrm{F}^{\geqslant \star}$ for this secondary filtration. On associated graded pieces,

$$
\operatorname{gr}_{\mathrm{F}}^{\star} \mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right) \simeq \operatorname{gr}_{\mathrm{F}}^{\star} \mathbf{Z}_{p}(i)\left(\mathbf{F}_{q}[z] / z^{n}\right)
$$

by the following proposition, and similarly for the other theories (by [4, Cor. 10.32]).
Proposition 2.6. Let $\mathrm{F}^{\geqslant \star} R$ and $\mathrm{F} \geqslant \star S$ be filtered quasisyntomic rings (in the sense that the associated $p$ completed Rees algebras are quasisyntomic over the $p$-completed Rees algebra of the trivial filtration on $\mathbf{Z}_{p}$ ). If the associated graded rings $\operatorname{gr}_{\mathrm{F}}^{\star} R$ and $\operatorname{gr}_{\mathrm{F}}^{\star} S$ are equivalent, then there is an induced equivalence

$$
\operatorname{gr}_{\mathrm{F}}^{\star} \underline{\Delta}_{R} \simeq \operatorname{gr}_{\mathrm{F}}^{\star} \underline{\Delta}_{S}
$$

and hence there are induced equivalences

$$
\operatorname{gr}_{\mathrm{F}}^{\star} \mathbf{Z}_{p}(i)(R) \simeq \operatorname{gr}_{\mathrm{F}}^{\star} \mathbf{Z}_{p}(i)(S)
$$

for each $i$.
Proof. See [4, Prop. 10.44, Cor. 10.45].
Remark 2.7. A similar use of filtrations is the basis of the work of Brun [14] and Angeltveit [2].
Mathew [35] (for $n=2$ and $p$ odd) and Sulyma [42] (in general) have computed the syntomic cohomology of truncated polynomial rings $R=k[z] / z^{n}$ when $k$ is a perfect field of characteristic $p$. In this case, prismatic cohomology agrees with crystalline cohomology. Since $R$ admits a flat lift to $W(k)$ together with a lift of Frobenius, one can compute $\Delta_{R}$ as a complex

$$
\begin{equation*}
\triangle_{R}^{\bullet}:\left(D_{\left(z^{n}\right)} W(k)[z] \xrightarrow{\mathrm{d}} D_{\left(z^{n}\right)} W(k)[z] \mathrm{d} z\right)_{p}^{\wedge}, \tag{3}
\end{equation*}
$$

the $p$-completion of the divided power de Rham complex. The Nygaard filtration $\mathrm{N} \geqslant \star \triangle_{R}$ is given by the Day convolution of the $p$-adic filtration on $\mathbf{Z}_{p}$ and the pd-Hodge filtration on $\Delta_{R}^{\bullet}$. (For characteristic $p$ rings such as $R$, the Breuil-Kisin twists are trivializable.)
Lemma 2.8. These presentations also compute the graded absolute prismatic cohomology of $R=k[z] / z^{n}$ together with its Nygaard filtration; see also [35, Ex. 8.11].

Proof. The lemma can be proved along the lines of [10, Prop. 8.7] by keeping track of the grading everywhere.

Lemma 2.9. Let $R=k[z] / z^{n}$ where $k$ is a perfect field of characteristic $p$.
(a) For $j>0, \operatorname{gr}_{\mathrm{F}}^{j} \widehat{\Delta}_{R}$ is concentrated in cohomological degree 1 , while $\operatorname{gr}_{\mathrm{F}}^{0} \widehat{\Delta}_{R} \simeq \widehat{\Delta}_{k} \simeq W(k)$.
(b) For $j>0, \operatorname{gr}_{\mathrm{F}}^{j} \mathrm{~N} \geqslant i \widehat{\Delta}_{R}$ is concentrated in cohomological degree 1, while $\operatorname{gr}_{\mathrm{F}}^{0} \mathrm{~N}^{\geqslant i} \widehat{\Delta}_{R} \simeq\left(p^{i}\right) \subseteq W(k)$ for $i \geqslant 0$.
(c) For $i \geqslant 1$, $\operatorname{gr}_{\mathrm{F}}^{j} \mathbf{Z}_{p}(i)(R)$ is in $\mathrm{D}\left(\mathbf{Z}_{p}\right)_{[-2,-1]}$ and vanishes for $j \geqslant$ in and for $j=0$.

Proof. See the computation in [42, Sec. 3], noting that in this case the Nygaard-completion and F-adic completion of $\Delta_{R}$ agree.
Remark 2.10. The F-adic filtration on $\widehat{\Delta}_{R}$ need not be complete for general filtered commutative rings $\mathrm{F}^{\star} R$, even if the filtration on $R$ is complete. Nevertheless, Proposition 2.11 implies that in good cases the induced filtration on syntomic cohomology is complete.

Proposition 2.11 (Completeness). Suppose that $\mathrm{F} \geqslant \star R$ is a complete filtered ring. If $\mathrm{F} \geqslant \star R$ is the filtered quotient of the completion of a finitely generated filtered polynomial ring by a filtered regular sequence, then the induced F-adic filtration on $\mathbf{Z}_{p}(i)(R)$ is complete.
Proof. It suffices to check the claim modulo $p$. However, modulo $p$, we can compute $\mathbf{Z}_{p}(i)(R) / p=\mathbf{F}_{p}(i)(R)$ as

$$
\mathbf{F}_{p}(i)(R) \simeq \operatorname{fib}\left(\frac{\mathrm{N}^{\geqslant i} \widehat{\triangle}_{R}\{i\} / p}{\mathrm{~N} \geqslant i+M \widehat{\mathbb{}}_{R}\{i\} / p} \xrightarrow{\operatorname{can}-\varphi} \frac{\widehat{\mathbb{}}_{R}\{i\} / p}{\mathrm{~N} \geqslant i+M \widehat{\triangle}_{R}\{i\} / p}\right)
$$

for $M$ sufficiently large by [10, Lem. 7.22] or [6, Cor. 5.31] or [4, Prop. 8.6]. The terms in the fiber sequence can be expressed via finitely many associated graded pieces of the Nygaard filtration on absolute prismatic cohomology (modulo $p$ ), which in turn can be expressed in terms of finitely many filtered pieces of the conjugate filtration $\mathrm{F}_{\leqslant \star}^{\mathrm{conj}} \bar{\triangle}_{R}\{i\}$ on absolute Hodge-Tate cohomology $\overline{\mathbb{}}_{R}\{i\}$. Finally, each filtered piece $\mathrm{F}_{\leqslant j}^{\text {conj }} \bar{\triangle}_{R}\{i\}$ can be expressed in terms of the finitely many filtered pieces of the conjugate filtration on the diffracted Hodge complex $\Omega_{R}^{\not p}$ of Bhatt-Lurie [8]. But, $\operatorname{gr}_{j}^{\mathrm{conj}} \Omega_{R}^{\not p} \simeq \widehat{\mathrm{~L}}_{R / \mathbf{Z}_{p}}^{j}[-j]$, the $(-j)$-fold shift of the $p$-complete derived absolute $j$-forms of $R$. It suffices now to use the fact that $L \Omega_{R / \mathbf{Z}_{p}}^{j}$ is complete for all $j$ by Lemma 2.12.

Lemma 2.12. Suppose that $\mathrm{F}^{\geqslant \star} R$ is a complete filtered ring. If $\mathrm{F} \geqslant \star R$ is the filtered quotient of the completion of a finitely generated filtered polynomial ring by a filtered regular sequence, then $\mathrm{L} \Omega_{R / \mathbf{Z}_{p}}^{j}$ is complete for each $j \geqslant 0$.

Proof. By hypothesis, $\mathrm{L}_{R / \mathbf{Z}_{p}}$ can be written as the cofiber of maps $\mathrm{F} \geqslant \star P_{1} \rightarrow \mathrm{~F} \geqslant \star P_{0}$ where $\mathrm{F} \geqslant \star P_{1}$ and $\mathrm{F} \geqslant \star P_{0}$ are filtered projective $\mathrm{F}^{\geqslant \star} R$-modules on finitely many generators. But, in this case, $\mathrm{L} \Omega_{R / \mathbf{Z}_{p}}^{j}$ has a finite increasing filtration with graded pieces $\mathrm{L} \Lambda^{a} P_{0} \otimes \mathrm{~L} \Lambda^{b}\left(P_{1}[1]\right) \simeq \mathrm{L} \Lambda^{a} P_{0} \otimes \mathrm{~L} \Gamma^{b}\left(P_{1}\right)[b]$ where $a+b=j$. Each of these is a (shift of a) filtered projective $\mathrm{F} \geqslant \star R$ module on finitely many generators. It follows that $\mathrm{L} \Omega_{R / \mathbf{Z}_{p}}^{j}$ is complete since $\mathrm{F}^{\geqslant \star} R$ is.

Corollary 2.13. If $R=\mathcal{O}_{K} / \varpi^{n}$ is given the $\varpi$-adic filtration, then
(i) the induced filtration $\mathrm{F}^{\geqslant \star} \mathbf{Z}_{p}(i)(R)$ on $\mathbf{Z}_{p}(i)(R)$ is complete for all $i$,
(ii) $\operatorname{gr}_{\mathrm{F}}^{j} \mathbf{Z}_{p}(i)(R)$ is in $\mathrm{D}\left(\mathbf{Z}_{p}\right)_{[-2,-1]}$ for $i \geqslant 1$ and vanishes for $j \geqslant$ in, and
(iii) $\operatorname{gr}_{\mathrm{F}}^{0} \mathbf{Z}_{p}(i)(R) \simeq 0$ for $i \geqslant 1$.

Proof. This follows from Proposition 2.11, Proposition 2.6, and Lemma 2.9.
The main result of this section is the following, which says that the weight $i$ syntomic cohomology of $\mathcal{O}_{K} / \varpi^{n}$ is concentrated in bounded F-weights. Later, this will permit us to work with the absolute prismatic cohomology of $R$ and its Nygaard filtration in bounded F -weights as well. For a filtered spectrum $\mathrm{F} \geqslant \star ~ M$ and integers $a \leqslant b$, we write $\mathrm{F}^{[a, b]}$ for the cofiber of $\mathrm{F} \geqslant b+1 M \rightarrow \mathrm{~F} \geqslant a$.

Corollary 2.14. For $i \geqslant 1$, there is a zig-zag of equivalences

$$
\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right) \rightarrow \mathrm{F}^{[0, i n-1]} \mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right) \leftarrow \mathrm{F}^{[1, i n-1]} \mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)
$$

Moreover, $\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right) \in \mathrm{D}\left(\mathbf{Z}_{p}\right)_{[-2,-1]}$.
Proof. This follows from Corollary 2.13.
Remark 2.15. One can extend the filtration bounds from Corollary 2.14 to a fairly general situation. Let $A$ be a filtered $\delta$-ring $A$ and $R$ a filtered $A$-algebra, and assume that the filtration of $R$ is concentrated in $[0, c]$ and that $L_{R / A}$ as an $R$-module has "filtered amplitude in $[a, b]$ ", i.e. can be built from copies of $R$ with filtration shifted by values in $[a, b]$. Then $\mathrm{L} \Omega_{R / A}^{j}$ has filtered amplitude in $[j a, j b]$, and an argument using the Nygaard and conjugate filtrations shows that the filtration on $\mathbf{Z}_{p}(i)(R / A)$ is concentrated in $[0,(i-1) b+c]$, i.e.

$$
\mathbf{Z}_{p}(i)(R / A) \simeq \mathrm{F}^{[0,(i-1) b+c]} \mathbf{Z}_{p}(i)(R / A)
$$

Corollary 2.16. For $i \geqslant 1$, $\mathrm{K}_{2 i-1}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right) \cong \mathrm{H}^{1}\left(\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)\right)$ and, for $i \geqslant 2, \mathrm{~K}_{2 i-2}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right) \cong$ $\mathrm{H}^{2}\left(\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)\right)$.

Proof. Indeed the motivic spectral sequence computing TC and hence $p$-adic K-theory degenerates for degree reasons and there are no possible extensions by Corollary 2.14.

Remark 2.17. The analogue of Corollary 2.16 holds in the limit for $\mathcal{O}_{K}$ as well. This can be proved from Corollary 2.16 using $p$-adic continuity for syntomic cohomology (see [8, Cor. 7.4.11]) and TC( $-; \mathbf{Z}_{p}$ ) (see [16, Thm. 5.20]), or it can be proved directly by using crystalline degeneration again to reduce to characteristic p.

Already, it is possible to extract qualitative information about the K-groups using crystalline degeneration for syntomic cohomology and Sulyma's calculation [42]. The following result was proved in the unramified case in [2].

Proposition 2.18 (Angeltveit quotient). For $i \geqslant 1$ and any finite chain ring $R=\mathcal{O}_{K} / \varpi^{n}$ with residue field $\mathbf{F}_{q}$,

$$
\frac{\left|\mathrm{H}^{1}\left(\mathbf{Z}_{p}(i)(R)\right)\right|}{\left|\mathrm{H}^{2}\left(\mathbf{Z}_{p}(i)(R)\right)\right|}=q^{i(n-1)}
$$

Proof. By Corollary 2.14,

$$
\mathbf{Z}_{p}(i)(R) \simeq \mathrm{fib}\left(\mathrm{~F}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\Delta}_{R}\{i\} \xrightarrow{\text { can- }} \mathrm{F}^{[1, i n-1]} \widehat{\triangle}_{R}\{i\}\right)
$$

On associated graded pieces,

$$
\bigoplus_{j=1}^{i n-1} \operatorname{gr}_{\mathrm{F}}^{j} \mathrm{~N}^{\geqslant i} \widehat{\triangle}_{R}\{i\} \simeq \bigoplus_{j=1}^{i n-1} \operatorname{gr}_{\mathrm{F}}^{j} \mathrm{~N}^{\geqslant i}{\widehat{{ }_{\triangle}^{\mathbf{F}}}}[z] / z^{n}
$$

(where the Breuil-Kisin twist is trivialized on the right as we are in the crystalline setting there) and similarly for $\mathrm{F}^{[1, i n-1]} \triangle_{R}\{i\}$.

By [42], $\operatorname{gr}_{\mathrm{F}}^{j} \widehat{\mathbb{}}_{\mathbf{F}_{q}[z] / z^{n}} \cong W\left(\mathbf{F}_{q}\right) /\{j, n\}[-1]$ for $j \geqslant 1$, where

$$
\{j, n\}= \begin{cases}n & \text { if } n \mid j \\ j & \text { otherwise }\end{cases}
$$

On the other hand, $\operatorname{gr}_{\mathbf{F}}^{j} \mathrm{~N}^{\geqslant i} \widehat{\triangle}_{\mathbf{F}_{q}[z] / z^{n}} \cong W\left(\mathbf{F}_{q}\right) / p^{\epsilon(i, j)}\{j, n\}[-1]$ for $j \geqslant 1$, where

$$
\epsilon(i, j)= \begin{cases}1 & \text { if }\left\lfloor\frac{j}{n}\right\rfloor<\left\lceil\frac{j}{n}\right\rceil \leqslant i \\ 0 & \text { otherwise }\end{cases}
$$

It follows that the quotient appearing in the statement of the proposition has order

$$
\prod_{j=1}^{i n-1} q^{\epsilon(i, j)}
$$

Note that $\epsilon(i, j)=1$ if and only if $j$ is not divisible by $n$. In the range $1, \ldots, i n-1$ there are $i-1$ numbers $j$ divisible by $n$. So, the product has order $q^{i n-1-(i-1)}=q^{i(n-1)}$, as desired.

Remark 2.19. Proposition 2.18 can be proved directly using the machinery of prismatic envelopes; see Lemma 4.65.

Finally, we observe that while $\triangle_{R / A}^{(1)}$ is generally not complete for either the F-filtration or the Nygaard filtration, the two completions are closely related.

Theorem 2.20. Let $R / A$ be a filtered prismatic $\delta$-pair.
(1) If $\mathrm{F}^{\geqslant \star} R$ is complete and $\mathrm{L}_{R / A}$ is a perfect filtered $R$-module (i.e. in the thick subcategory generated by filtered shifts of $R$ ), then the Nygaard-completion of $\triangle_{R / A}^{(1)}$ is also F-complete.
(2) If $\mathrm{gr}^{0} R$ is smooth over $\mathrm{gr}^{0} \bar{A}$, then the F -completion of $\Delta_{R / A}^{(1)}$ is also Nygaard-complete.

Proof. For the first statement, it suffices to check that each term in the Nygaard associated graded is F-complete, since this exhibits the Nygaard completion as limit of F-complete objects. As $\operatorname{gr}_{\mathrm{N}}^{i} \triangle_{R / A}^{(1)} \simeq$ $\mathrm{F}_{\leqslant i}^{\text {conj }} \bar{\Delta}_{R / A}$, it suffices to check that each of the $\operatorname{gr}_{i}^{\text {conj }} \bar{\Delta}_{R / A} \simeq \widehat{\mathrm{~L} \Omega}_{R / A}^{i}[-i]$ is F-complete. By assumption, $\mathrm{L}_{R / A}$ is a perfect filtered $R$-module, so the same is true for each of its exterior powers. Since $\mathrm{F}^{\geqslant \star} R$ is complete, the $\widehat{\mathrm{L} \Omega}_{R / A}^{i}[-i]$ are all complete.

For the second statement, we need to prove that each term in the F-associated graded is Nygaard-complete. To do so, we observe that there is a limit $\mathrm{N}^{\geqslant \star} \triangle_{R / A}^{(1)} \simeq \lim _{j}\left(\mathrm{~N} \geqslant \star \triangle_{R / A}^{(1)} \otimes_{I^{\star} A}\left(I^{\star} A / I^{j} A\right)\right)$ in $(p, I)$-complete filtered complexes: this follows from $I$-completeness of $\Delta_{R / A}^{(1)}$ upon forgetting the Nygaard filtration and from the fact that the filtration is eventually constant in each weight on the Nygaard associated graded pieces. It is now enough to show that each $\operatorname{gr}_{\mathrm{F}}^{k}\left(\mathrm{~N}^{\geqslant \star} \triangle_{R / A}^{(1)} \otimes_{I^{\star} A}\left(I^{\star} A / I^{j} A\right)\right)_{p}^{\wedge}$ is a complete filtration and for this we
can reduce to the case when $j=1$. Recall that the filtered tensor product $\left(\mathrm{N} \geqslant \star \triangle_{R / A}^{(1)} \otimes_{I^{\star} A} A / I\right)_{p}^{\wedge}$ agrees with the Hodge filtration on $p$-complete derived de Rham cohomology, for example by [32, Thm. 1.8] or [8, Cor. 5.2.8]. We prove the following stronger claim: if $r$ is an upper bound for the rank of the projective $\operatorname{gr}_{\mathrm{F}}^{0} R-$ module $\mathrm{L}_{\mathrm{gr}_{\mathrm{F}} R / \operatorname{gr}_{\mathrm{F}}^{0} A}$, then the induced Nygaard/Hodge filtration on $\operatorname{gr}_{\mathrm{F}}^{h}\left(\triangle_{R / A}^{(1)} \otimes_{I^{\star} A} A / I\right)_{p}^{\wedge} \simeq \operatorname{gr}_{\mathrm{F}}^{h}\left(\mathrm{dR}_{R / \bar{A}}\right)_{p}^{\wedge}$ is bounded by $h+r$ for each $h \geqslant 0$. Indeed, this statement can be checked after base change along $A \rightarrow \operatorname{gr}_{\mathrm{F}}^{0} A$, so we may assume the F-filtration on $A$ to be trivial. We may also pass to the F -associated graded to assume that $R$ is in fact graded instead of just filtered. Finally, we may write any graded $A$-algebra with the given smooth degree 0 part as sifted colimit of smooth graded $A$-algebras, constant on the degree 0 part. So the statement is reduced to the case where $R$ is graded smooth over $A$, and $\operatorname{gr}_{\mathrm{F}}^{0} R$ has relative dimension bounded by $r$. In that case, the $p$-completed derived de Rham complex $\left(\mathrm{dR}_{R / \bar{A}}\right)_{p}^{\wedge}$ is in fact Hodge-complete (see for example [8, Prop. E.12]) and $\widehat{\mathrm{L} \Omega}_{R / \bar{A}}^{h}$ has F-filtration bounded below by $h-r$ since $\widehat{\mathrm{L} \Omega}_{\mathrm{gr}_{\mathrm{F}}^{0} R / \bar{A}}^{j}$ vanishes for $j>r$. Thus, $\operatorname{gr}_{\mathrm{F}}^{h}\left(\triangle_{R / A}^{(1)} \otimes_{I^{\star} A} A / I\right)_{p}^{\wedge}$ has Nygaard/Hodge filtration bounded above by $h+r$, as claimed.

### 2.3 Relative-to-absolute descent

In order to compute the syntomic complexes, we will compute part of the prismatic cohomology of $\mathcal{O}_{K} / \varpi^{n}$. Specifically, by Corollary 2.14, it is enough to compute

$$
\mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\triangle}_{\mathcal{O}_{K} / \varpi^{n}}\{i\} \quad \text { and } \quad \mathrm{F}^{[1, i n-1]}{\widehat{{ }_{\mathcal{O}}^{K}}} \varpi_{\varpi^{n}}\{i\}
$$

and the canonical and Frobenius maps between these complexes. Unfortunately, these absolute prismatic cohomological objects are not abelian groups but objects of $\mathrm{D}\left(\mathbf{Z}_{p}\right)$ concentrated in cohomological degrees 0 and 1. However, by working relative to the Breuil-Kisin prism $W(k) \llbracket z_{0} \rrbracket$, where $z_{0}$ maps to $\varpi$, the analogous relative terms become discrete, i.e., they are abelian groups and admit algebraic descriptions in the form of prismatic envelopes. The absolute prismatic cohomology can then be understood via descent along $W(k) \rightarrow W(k) \llbracket z_{0} \rrbracket$ using that $\unlhd_{R / \mathbf{z}_{p}} \simeq_{\triangle_{R / W(k)}}$ by [4, Thm. 1.2]. This is a complementary approach to the quasisyntomic descent introduced in [10] and was introduced, for THH and its variants, by Liu and Wang in [33]. ${ }^{2}$

In more detail, we consider the cosimplicial $\delta$-ring $A^{\bullet}$ given by taking the $p$-complete Amitsur complex of $W(k) \rightarrow W(k)\left\langle z_{0}\right\rangle$ and completing each term with respect to the augmentation ideal given by mapping to the constant cosimplicial diagram $\mathbf{Z}_{p}$ induced by sending $z_{0}$ to zero. In other words, $A^{\bullet}$ is

$$
W(k) \llbracket z_{0} \rrbracket \rightleftarrows W(k) \llbracket z_{0}, z_{1} \rrbracket \Longleftrightarrow \cdots
$$

Moreover, $A^{\bullet}$ is a cosimplicial filtered $\delta$-ring in the sense of [4, Sec. 10], where each $A^{s}$ is given the filtration where $z_{0}, \ldots, z_{s}$ have weight 1 and where $\delta\left(z_{0}\right)=\cdots=\delta\left(z_{s}\right)=0$. There is a filtered map from $A^{\bullet}$ to $\mathcal{O}_{K} / \varpi^{n}$, given by sending each of $z_{0}, \ldots, z_{s}$ to $\varpi$, which makes $\left(A^{\bullet}, \mathcal{O}_{K} / \varpi^{n}\right)$ into a cosimplicial filtered $\delta$-pair.

Construction 2.21. In [4], we introduce relative syntomic complexes

$$
\mathbf{Z}_{p}(i)(R / A) \simeq \operatorname{fib}\left(\mathrm{N}^{\geqslant i} \widehat{\triangle}_{R / A}^{(1)}\{i\} \xrightarrow{\text { can }-\varphi} \widehat{\mathbb{}}_{R / A}^{(1)}\{i\}\right)
$$

for any $i \in \mathbf{Z}$, which can be defined from the prismatic package $\underline{\Delta}_{R / A}$ of any $\delta$-pair $(A, R)$. In the case of a filtered $\delta$-pair, there is an induced natural filtration $\mathrm{F}^{\star} \mathbf{Z}_{p}(i)(R / A)$ on the relative syntomic complex.

The following theorem follows from our work in [4].
Theorem 2.22 (Relative-to-absolute descent). Let $R=\mathcal{O}_{K} / \varpi^{n}$. The following maps are equivalences:

[^1](a) $\mathrm{F}^{\geqslant \star} \mathbb{\triangle}_{R / W(k)}\{i\} \rightarrow \operatorname{Tot} \mathrm{F}^{\geqslant \star} \triangle_{R / A} \bullet\{i\}$ for all $i \in \mathbf{Z}$;
(b) $\mathrm{F} \geqslant{ }^{\geqslant} \mathrm{N} \geqslant j \widehat{\widehat{\triangle}}_{R / W(k)}^{(1)}\{i\} \rightarrow \operatorname{Tot} \mathrm{F} \geqslant \star \mathrm{N} \geqslant j \widehat{\widehat{\Delta}}_{R / A}^{(1)} \cdot\{i\}$ for all $i, j \in \mathbf{Z}$;
(c) $\mathrm{F}^{\geqslant \star} \mathbf{Z}_{p}(i)(R) \rightarrow \operatorname{Tot} \mathrm{F}^{\geqslant \star} \mathbf{Z}_{p}(i)\left(R / A^{\bullet}\right)$ for all $i \in \mathbf{Z}$;
(d) $\mathrm{F}^{[a, b]} \mathbf{Z}_{p}(i)(R) \rightarrow \operatorname{Tot} \mathrm{F}^{[a, b]} \mathbf{Z}_{p}(i)\left(R / A^{\bullet}\right)$ for all integers $i \geqslant 1$ and all intervals $[a, b] \subseteq \mathbf{Z}$.

Proof. Part (d) follows from part (c), which follows from (a) and (b). On $\mathrm{F}^{0}$, parts (a) and (b) follow from [4, Thm. 1.1 and Cor. 1.2]. Therefore, to prove (a) and (b) it is enough to check on F-associated graded pieces and even on the F-associated graded pieces of the Hodge-Tate and the Nygaard filtrations, where it follows from descent for the graded cotangent complex.

Proposition 2.23 (Cosimplicial prismatic envelope). The cosimplicial filtered $\delta$-ring $\mathrm{F} \geqslant \star \triangle_{R / A} \cdot$ is discrete; the same is true for $\mathrm{F} \geqslant * \mathrm{~N} \geqslant i \widehat{\Delta}_{R / A}^{(1)}$. and $\mathrm{F} \geqslant \star \widehat{\triangle}_{R / A}^{(1)} \bullet$.

Proof. For $\triangle_{R / A} \bullet$ the levelwise discreteness follows from [11, Prop. 3.13] and for $\mathrm{F}^{\star} \mathbb{\Delta}_{R / A} \bullet$ it follows from [4, Prop. 10.41]. For $\mathrm{F}^{\geqslant \star} \mathrm{N}^{\geqslant i} \widehat{\triangle}_{R / A}^{(1)}$, one reduces, using the conjugate filtration, to the fact $\mathrm{L}_{R / A} \bullet[-1]$ is a levelwise flat filtered $R$-module.

Proposition 2.24 (Cosimplicial freeness). For $[a, b] \subseteq \mathbf{Z}$, both $\mathrm{F}^{[a, b]} \mathrm{N}^{\geqslant i} \widehat{\triangle}_{R / A}^{(1)}\{i\}$ and $\mathrm{F}^{[a, b]} \widehat{\triangle}_{R / A}^{(1)} \bullet\{i\}$ are cosimplicial $\mathbf{Z}_{p}$-modules which are levelwise finite and free.

Proof. This follows from Proposition 2.23 and Proposition 3.34.
Proposition 2.25. Let $R=\mathcal{O}_{K} / \varpi^{n}$. Then, $\operatorname{gr}_{\mathrm{F}}^{j} \widehat{\Delta}_{R}\{i\}$ and $\operatorname{gr}_{\mathrm{F}}^{j} \mathrm{~N} \geqslant i \widehat{\Delta}_{R}\{i\}$ are in $\mathrm{D}\left(\mathbf{Z}_{p}\right)_{[-1,-1]}$ for each $j, i \geqslant 1$.

Proof. See Proposition 2.6 and Lemma 2.9.
Proof. By Proposition 3.34, all terms are finitely generated free $W(k)$-modules of the same ranks. The map is an injection as is seen by rewriting $z_{0}^{n}$ in terms of $f_{00}$. Thus, it is an isogeny.

Lemma 2.26. For $R=\mathcal{O}_{K}$ or $\mathcal{O}_{K} / \varpi^{n}$, the limits $\mathrm{F}^{[a, b]} \mathrm{N} \geqslant i \widehat{\triangle}_{R}\{i\}$ and $\mathrm{F}^{[a, b]} \widehat{\triangle}_{R}\{i\}$ of the descent diagrams

$$
\mathrm{F}^{[a, b]} \mathrm{N}^{\geqslant i} \widehat{\triangle}_{R / A^{0}}^{(1)}\{i\} \Longleftrightarrow \cdots
$$

and

$$
\mathrm{F}^{[a, b]} \widehat{\triangle}_{R / A^{0}}^{(1)}\{i\} \Longleftrightarrow \cdots
$$

have finitely generated torsion cohomology groups for each $i \in \mathbf{Z}$ and each finite interval $[a, b] \subseteq \mathbf{Z}$ with $a \geqslant 1$.

Proof. This follows from a crystalline degeneration argument. For example, the associate graded of the $\varpi$-adic filtration on $\mathcal{O}_{K}$ is $k \llbracket z_{0} \rrbracket$. Its prismatic cohomology agrees with its crystalline cohomology, but, as it admits a lift to $W(k)$, its crystalline cohomology is identified with the de Rham cohomology of the lift, which is computed by the complex

$$
W(k) \llbracket z_{0} \rrbracket \xrightarrow{\mathrm{~d}} W(k) \llbracket z_{0} \rrbracket \mathrm{~d} z_{0} .
$$

Restricting to F-filtration $[a, b]$ amounts to restricting to the subcomplex

$$
W(k) \cdot\left\{z_{0}^{a}, \ldots, z_{0}^{b}\right\} \xrightarrow{\mathrm{d}} W(k) \cdot\left\{z_{0}^{a-1} \mathrm{~d} z_{0}, \cdots, z_{0}^{b-1} \mathrm{~d} z_{0}\right\},
$$

which has finitely generated torsion cohomology, since $a \geqslant 1$. The other cases are left to the reader.

### 2.4 A finite complex computing syntomic cohomology

In the absolute case, $\mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant \widehat{\Delta}_{R}\{i\}$ and $\mathrm{F}^{[1, i n-1]} \widehat{\triangle}_{R}\{i\}$ are each in $\mathrm{D}\left(\mathbf{Z}_{p}\right)_{[-1,-1]}$ for $i \geqslant 1$ by Propositions 2.6 and 2.25 , so the cochain complexes associated to the cosimplicial abelian groups

$$
\mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\triangle}_{R / A}^{(1)} \cdot\{i\} \quad \text { and } \quad \mathrm{F}^{[1, i n-1]} \widehat{\triangle}_{R / A}^{(1)} \cdot\{i\}
$$

are exact in cohomological degrees at least 2.
It follows that we can compute $\mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\Delta}_{R}$ as the fiber of an injective map

$$
\begin{equation*}
\mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\Delta}_{R / A^{0}}^{(1)}\{i\} \rightarrow \operatorname{ker}\left(\mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\Delta}_{R / A^{1}}^{(1)}\{i\} \xrightarrow{d^{0}-d^{1}+d^{2}} \mathrm{~F}^{[1, i n-1]} \mathrm{N}^{\geqslant} \geqslant \widehat{\triangle}_{R / A^{2}}^{(1)}\{i\}\right) \tag{4}
\end{equation*}
$$

and similarly for $\mathrm{F}^{[1, i n-1]} \widehat{\Delta}_{R}\{i\}$.
Lemma 2.26 implies that $\mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\Delta}_{R}\{i\}$ and $\mathrm{F}^{[1, i n-1]} \widehat{\Delta}_{R}\{i\}$ are finitely generated torsion abelian groups, while Proposition 2.24 implies that the terms in (4) have the same rank over $\mathbf{Z}_{p}$.

We summarize the reductions of this section in the following theorem.
Theorem 2.27. For each $i \geqslant 1$, the complex $\mathbf{Z}_{p}(i)(R) \simeq \mathrm{F}^{[1, i n-1]} \mathbf{Z}_{p}(i)(R)$ is equivalent to the total complex (i.e., total fiber) of the commutative square

$$
\begin{aligned}
& \mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\triangle}_{R / A^{0}}^{(1)}\{i\} \longrightarrow \operatorname{ker}\left(\mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\mathbb{}}_{R / A^{1}}^{(1)}\{i\} \xrightarrow{d^{0}-d^{1}+d^{2}} \mathrm{~F}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\triangle}_{R / A^{2}}^{(1)}\{i\}\right) \\
& \operatorname{can}-\varphi \downarrow \operatorname{can}-\varphi \downarrow \\
& \mathrm{F}^{[1, i n-1]} \widehat{\triangle}_{R / A^{0}}^{(1)}\{i\} \longrightarrow \operatorname{ker}\left(\mathrm{F}^{[1, i n-1]} \widehat{\triangle}_{R / A^{1}}^{(1)}\{i\} \xrightarrow{d^{0}-d^{1}+d^{2}} \mathrm{~F}^{[1, i n-1]} \widehat{\Delta}_{R / A^{2}}^{(1)}\{i\}\right) .
\end{aligned}
$$

To compute the total complex of Theorem 2.27, we analyze the prismatic cohomology of $R$ over $A^{0}$ and $A^{1}$ via the prismatic envelopes introduced in [11]. This lets us find bases of all of the terms involved and to compute the maps between them; see Sections 3 and 4.1. Moreover, we identify in Corollary 4.44 the horizontal maps with a kind of 'connection' on $\widehat{\triangle}_{R / A^{0}}^{(1)}\{i\}$, not unlike the description of prismatic cohomology of $k[z] / z^{n}$ in equation (3).

## 3 Envelope algebra

In [11], Bhatt and Scholze give a prismatic envelope description of $\triangle_{R / A}$ when $(A, d)$ is a bounded, oriented prism and $R=A /(d, r)$, where $r \in A$ is an element which defines a non-zero divisor in $\bar{A}=A / d$. The description is as a "prismatic envelope", which is defined as the ( $p, d$ )-completion of a pushout

in $\delta$ - $A$-algebras, where $A\{a\}$ denotes the free $\delta$ - $A$-algebra on a generator $a .{ }^{3}$ We write $A\left\{\frac{r}{d}\right\}$ for the pushout and $A\left\{\frac{r}{d}\right\}_{\hat{p}, d}$ for its completion. The result is a flat $\delta$ - $A$-algebra and the construction commutes with base change of maps of bounded, oriented prisms by [11, Prop. 3.13]. Given an object $(B, I)$ in the relative prismatic site $(R / A)_{\Delta}$, one has that $R$ maps to $\bar{B}=B / I$ so that the image of $r$ in $B$ must be divisible by $I$. Using that $I=d B$ and writing $r=d a \in I$ for some unique $a$, we see there is a natural induced map $A\left\{\frac{r}{d}\right\}_{p, d} \rightarrow B$ of prisms over $A$. Bhatt and Scholze show that in fact $A\left\{\frac{r}{d}\right\}_{p, d}$ represents a final object of $(R / A)_{\triangle}$ so that $\triangle_{R / A} \simeq A\left\{\frac{r}{d}\right\}_{p, d}$.

[^2]In this section, we examine the algebra of the construction of $A\left\{\frac{r}{d}\right\}_{p, d}^{\wedge}$ and closely-related variants. In particular, we show that, as a commutative ring, the prismatic envelope is the ( $p, d$ )-completed quotient of a countably generated polynomial ring over $A$ by countably many relations which are ( $p, d)$-completely Koszul-regular. Then, we give generators and relations descriptions of

$$
\mathrm{F}_{\leqslant \star}^{\mathrm{conj}} \bar{\Delta}_{R / A}, \quad \operatorname{gr}_{\mathrm{N}}^{\star} \widehat{\triangle}_{R / A}^{(1)}, \quad \text { and } \quad \mathrm{N}^{\geqslant \star} \widehat{\Delta}_{R / A}^{(1)}
$$

as increasingly filtered, graded, and decreasingly filtered commutative rings. This allows us to give additive generators of these objects. When $A=W(k) \llbracket z_{0}, \ldots, z_{s} \rrbracket$ is viewed as filtered prism with respect to some Eisenstein polynomial $E\left(z_{j}\right)$ where $z_{0}, \ldots, z_{s}$ have weight 1 and when $R=\mathcal{O}_{K}$ or $\mathcal{O}_{K} / \varpi^{n}$, then we give additive bases for the filtered pieces $\mathrm{F}^{[a, b]} \mathrm{N} \geqslant i \widehat{\triangle}_{R / A}^{(1)}$. Eventually, these additive bases are how we will compute the syntomic cohomology of $\mathcal{O}_{K} / \varpi^{n}$.

Notation 3.1. Throughout this section, we consider filtered rings and modules. Here we will often think of a decreasingly filtered module $\mathrm{F}^{\geqslant \star} M$ as a graded module $\bigoplus_{i \in \mathbf{Z}} \mathrm{~F}^{\geqslant i} M$ together with an action by the graded ring $\mathbf{Z}[\tau]$, where $\tau$ acts by the transition maps $\mathrm{F}^{\geqslant i} M \rightarrow \mathrm{~F} \geqslant i-1$.

### 3.1 Some formulas about $\delta$

Recall the following facts about $\delta$-rings $A$. We have

$$
\begin{equation*}
\delta(x+y)=\delta(x)+\delta(y)+w_{1}(x, y) \tag{5}
\end{equation*}
$$

for all $x, y \in A$, where

$$
\begin{equation*}
w_{1}(x, y)=\left(x^{p}+y^{p}-(x+y)^{p}\right) / p=-\left(\sum_{j=1}^{p-1}\binom{p}{j} x^{j} y^{p-j}\right) / p \tag{6}
\end{equation*}
$$

a polynomial in $x$ and $y$ with integer coefficients. If $x, y \in A$, then

$$
\begin{align*}
\delta(x y) & =\delta(x) y^{p}+x^{p} \delta(y)+p \delta(x) \delta(y)  \tag{7}\\
& =\delta(x) y^{p}+\varphi(x) \delta(y)  \tag{8}\\
& =\delta(x) \varphi(y)+x^{p} \delta(y) . \tag{9}
\end{align*}
$$

If $x \in A$, then

$$
\begin{equation*}
\varphi(x) \in(p, x) \tag{10}
\end{equation*}
$$

since $\varphi(x)=x^{p}+p \delta(x)$.
Lemma 3.2. If $A$ is a $\delta$-ring and $x, y \in A$, then

- $\delta(x+y)=\delta(x)+\delta(y)(\bmod x)$,
- $\delta(x-y)=\delta(x)-\delta(y)(\bmod x-y)$, and
- $\delta(x y)=\delta(x) \varphi(y)(\bmod x)$.

Proof. These relations follow from the addition and multiplication formulas for $\delta$.
Lemma 3.3. If $A$ is a $\delta$-ring, then $\delta\left(x^{p}\right)=0(\bmod p)$ for all $x \in A$.
Proof. Use $x^{p^{2}}+p \delta\left(x^{p}\right)=\varphi\left(x^{p}\right)=\varphi(x)^{p}=\left(x^{p}+p \delta(x)\right)^{p}$ to prove the lemma in the free $\delta$-ring on one generator $x$, which is $p$-torsion free, and deduce it in general.
Lemma 3.4. If $A$ is a $\delta$-ring, then $\delta\left(u x^{p}\right)=\delta(u) x^{p^{2}}(\bmod p)$ for all $u, x \in A$.
Proof. Indeed, $\delta\left(u x^{p}\right)=\delta(u) x^{p^{2}}+\varphi(u) \delta\left(x^{p}\right)=\delta(u) x^{p^{2}}(\bmod p)$ by Lemma 3.3.

### 3.2 Prismatic envelopes

Definition 3.5 (Koszul-regularity). Say that a sequence $\left(x_{0}, x_{1}, \ldots\right)$ of elements in a commutative ring $R$ is Koszul-regular if the associated Koszul complex $K\left(x_{\bullet}\right)$ has homology concentrated in degree 0 , in which case it is a resolution of $R /\left(x_{0}, x_{1}, \ldots\right)$. Koszul-regularity is implied by regularity. If $I \subseteq R$ is a finitely generated ideal, then such a sequence is called $I$-completely Koszul-regular if the $I$-completed Koszul complex $K\left(x_{\bullet}\right)_{I}^{\wedge}$ has homology concentrated in degree 0 , in which case it is a resolution of the derived $I$-adic completion of $R /\left(x_{0}, x_{1}, \ldots\right)$.

Lemma 3.6. Let $(A, d)$ be an oriented prism and fix elements $a, r \in A$. Let $\lambda_{0}=-\frac{1}{\delta(d)}$ and $R_{0}=\frac{\delta(r)}{\delta(d)}$ and inductively define elements

$$
\lambda_{u+1}=\frac{\lambda_{u}^{p}}{1-\delta\left(d^{p^{u+1}} \lambda_{u}\right)}
$$

and

$$
R_{u+1}=\frac{1}{1-\delta\left(d^{p^{u+1}} \lambda_{u}\right)}\left(\delta\left(R_{u}\right)+w_{1}\left(d^{p^{u+1}} \lambda_{u} \delta^{u+1}(a), R_{u}\right)\right)
$$

for $u \geqslant 0$. Then, the following statements hold.
(i) The elements $R_{u}$, for $u \geqslant 0$, are polynomials in the $\delta$-powers $\delta^{j}(a)$ for $j \leqslant u$ (with coefficients in $\left.\mathbf{Z}_{p}\{d, r\}\left[\delta(d)^{-1}\right]_{p, d}\right)$, of total degree $<p^{u+1}$ with respect to the grading where $\left|\delta^{j}(a)\right|=p^{j}$. In particular, $R_{u}$ involves only powers of $\delta^{u}(a)$ with exponent $<p$.
(ii) The elements $\lambda_{u}$ are units in $A$ for $u \geqslant 0$.
(iii) The $\delta$-ideal $(d a-r)_{\delta}$ agrees with the ideal generated $b y(d a-r)$ and the elements

$$
\delta^{u}(a)^{p}-\left(-p+d^{p^{u+1}} \lambda_{u}\right) \delta^{u+1}(a)-R_{u}
$$

Proof. To prove (iii), observe that

$$
\delta^{u}(a)^{p}-\left(-p+d^{p^{u+1}} \lambda_{u}\right) \delta^{u+1}(a)-R_{u}=\varphi\left(\delta^{u}(a)\right)-d^{p^{u+1}} \lambda_{u} \delta^{u+1}(a)-R_{u} .
$$

We write $I_{u}$ for the ideal

$$
\left(d a-r, \delta(d a-r), \ldots, \delta^{u}(d a-r)\right)
$$

To prove that $(d a-r)_{\delta}=\bigcup I_{u}$ agrees with the ideal generated by $(d a-r)$ and the elements $\varphi\left(\delta^{u}(a)\right)-$ $d^{p^{u+1}} \lambda_{u} \delta^{u+1}(a)-R_{u}$, we claim there exist units $\mu_{u}$ with

$$
\delta^{u+1}(d a-r)=\mu_{u}\left(\varphi\left(\delta^{u}(a)\right)-d^{p^{u+1}} \lambda_{u} \delta^{u+1}(a)-R_{u}\right) \quad\left(\bmod I_{u}\right)
$$

This in particular implies

$$
I_{u+1}=I_{u}+\left(\delta^{u+1}(d a-r)\right)=I_{u}+\left(\varphi\left(\delta^{u}(a)\right)-d^{p^{u+1}} \lambda_{u} \delta^{u+1}(a)-R_{u}\right)
$$

which is what we want to prove. To prove the claim, we proceed by induction. We will make repeated use of Lemma 3.2 Observe that

$$
\delta(d a-r)=\delta(d a)-\delta(r) \quad(\bmod d a-r)
$$

and

$$
\delta(d a)-\delta(r)=\delta(d) \varphi(a)+d^{p} \delta(a)-\delta(r)=\delta(d) \cdot\left(\varphi(a)-d^{p} \lambda_{0} \delta(a)-R_{0}\right)
$$

showing the claim for $u=0$ (with $\mu_{0}=\delta(d)$ ).
For the inductive step, assume the claim for $u$. Observe that $\delta\left(I_{u}\right) \subseteq I_{u+1}$, so

$$
\delta^{u+2}(d a-r)=\delta\left(\mu_{u}\left(\varphi\left(\delta^{u}(a)\right)-d^{p^{u+1}} \lambda_{u} \delta^{u+1}(a)-R_{u}\right)\right) \quad\left(\bmod I_{u+1}\right)
$$

Next, using Lemma 3.2, we find that

$$
\begin{aligned}
\delta\left(\mu_{u}\left(\varphi\left(\delta^{u}(a)\right)-d^{p^{u+1}} \lambda_{u} \delta^{u+1}(a)-R_{u}\right)\right) & =\varphi\left(\mu_{u}\right) \delta\left(\varphi\left(\delta^{u}(a)\right)-d^{p^{u+1}} \lambda_{u} \delta^{u+1}(a)-R_{u}\right) \quad\left(\bmod I_{u+1}\right) \\
& =\varphi\left(\mu_{u}\right)\left(\delta\left(\varphi\left(\delta^{u}(a)\right)-\delta\left(d^{p^{u+1}} \lambda_{u} \delta^{u+1}(a)+R_{u}\right)\right) \quad\left(\bmod I_{u+1}\right)\right.
\end{aligned}
$$

using that $\varphi\left(\delta^{u}(a)\right)-d^{p^{u+1}} \lambda_{u} \delta^{u+1}(a)-R_{u} \in I_{u+1}$.
Now $\delta\left(\varphi\left(\delta^{u}(a)\right)\right)=\varphi\left(\delta^{u+1}(a)\right)$, and

$$
\delta\left(d^{p^{u+1}} \lambda_{u} \delta^{u+1}(a)+R_{u}\right)=\delta\left(d^{p^{u+1}} \lambda_{u}\right) \varphi\left(\delta^{u+1}(a)\right)+d^{p^{u+2}} \lambda_{u}^{p} \delta^{u+2}(a)+\delta\left(R_{u}\right)+w_{1}\left(d^{p^{u+1}} \lambda_{u} \delta^{u+1}(a), R_{u}\right)
$$

Their difference can be factored as

$$
\begin{aligned}
& \delta\left(\varphi\left(\delta^{u}(a)\right)\right)-\delta\left(d^{p^{u+1}} \lambda_{u} \delta^{u+1}(a)+R_{u}\right) \\
& =\varphi\left(\delta^{u+1}(a)\right)-\left(\delta\left(d^{p^{u+1}} \lambda_{u}\right) \varphi\left(\delta^{u+1}(a)\right)+d^{p^{u+2}} \lambda_{u}^{p} \delta^{u+2}(a)+\delta\left(R_{u}\right)+w_{1}\left(d^{p^{u+1}} \lambda_{u} \delta^{u+1}(a), R_{u}\right)\right) \\
& =\left(1-\delta\left(d^{p^{u+1}} \lambda_{u}\right)\right) \cdot\left(\varphi\left(\delta^{u+1}(a)\right)-d^{p^{u+2}} \lambda_{u+1} \delta^{u+2}(a)-R_{u+1}\right),
\end{aligned}
$$

using the definition of $\lambda_{u+1}$ and $R_{u+1}$, which completes the inductive step (with $\mu_{u+1}=\varphi\left(\mu_{u}\right) \cdot(1-$ $\left.\delta\left(d^{p^{u+1}} \lambda_{u}\right)\right)$ ).

Part (i) follows easily from the provided recursion, working in the graded $\delta$-ring

$$
\mathbf{Z}_{p}\{d, r, a\}\left[\delta(d)^{-1}\right]_{p, d}^{\wedge}
$$

where $|a|=1$ and $|d|=|r|=0$. Part (ii) follows inductively from Lemma 3.2.
Remark 3.7. If $\delta(r)=0$, observe that the $R_{u}$ are all inductively zero.
Proposition 3.8. Let $A$ be a bounded prism with orientation $I=(d)$ and let $r_{1}, \ldots, r_{c} \in A$ map to a p-completely Koszul-regular sequence in $\bar{A}=A / d$. Then, the prismatic envelope $A\left\{\frac{r_{1}}{d}, \ldots, \frac{r_{c}}{d}\right\}_{(p, d)}=$ $\left(A\left\{a_{1}, \ldots, a_{c}\right\} /\left(d a_{1}-r_{1}, \ldots, d a_{c}-r_{c}\right)_{\delta}\right)_{(p, d)}^{\wedge}$ is the quotient of the $(p, d)$-complete free $\delta$-ring $A\left\{a_{1}, \ldots, a_{c}\right\}_{(p, d)}^{\wedge}$ on generators $a_{1}, \ldots, a_{c}$ by the ( $\left.p, d\right)$-completely Koszul-regular sequence of relations

$$
\left(d a_{1}-r_{1}, \ldots, d a_{c}-r_{c}\right)
$$

and

$$
\delta^{u}\left(a_{v}\right)^{p}-\left(-p+d^{p^{u+1}} \lambda_{u}\right) \delta^{u+1}\left(a_{v}\right)-R_{u v}
$$

for $u \geqslant 0$ and $1 \leqslant v \leqslant c$, where $R_{u v}$ is the polynomial from Lemma 3.6 (for $a=a_{v}$ and $r=r_{v}$ ).
Proof. By Lemma 3.6, the $\delta$-ideal $\left(d a_{1}-r_{1}, \ldots, d a_{v}-r_{v}\right)_{\delta}$ agrees with the ideal generated by $\left(d a_{1}-\right.$ $\left.r_{1}, \ldots, d a_{c}-r_{c}\right)$ and the $\delta^{u}\left(a_{v}\right)^{p}-\left(-p+d^{p^{u+1}} \lambda_{u}\right) \delta^{u+1}\left(a_{v}\right)-R_{u v}$.

Thus it suffices to prove that these form a $(p, d)$-completely Koszul-regular sequence in $A\left[\delta^{u}\left(a_{v}\right) \mid u \geqslant\right.$ $0,1 \leqslant v \leqslant c]_{p, d}^{\wedge}$. It suffices to do this after base change to $\bar{A}=A / d$ and hence it suffices to prove that the images of the elements

$$
\delta^{u}\left(a_{v}\right)^{p}-\left(-p+d^{p^{u+1}} \lambda_{u}\right) \delta^{u+1}\left(a_{v}\right)-R_{u v}=\delta^{u}\left(a_{v}\right)^{p}+p \delta^{u+1}\left(a_{v}\right)-R_{u v}
$$

form a $p$-completely Koszul-regular sequence in $R\left[\delta^{u}\left(a_{v}\right) \mid u \geqslant 0,1 \leqslant v \leqslant c\right]_{p}^{\wedge}$. This ring admits an ascending filtration where $\delta^{u}\left(a_{v}\right)$ is in filtration $\leqslant p^{u}$. With respect to that filtration, $R_{u v}$ has filtration strictly smaller $p^{u+1}$, as discussed in Lemma 3.6. As the leading terms with respect to this filtration

$$
\delta^{u}\left(a_{v}\right)^{p}+p \delta^{u+1}\left(a_{v}\right)
$$

of the relations form a regular sequence, the relations do too.

Proposition 3.9. Let $(A,(d))$ be a bounded, oriented prism and let $r_{1}, \ldots, r_{c} \in A$ be elements which map to a p-completely Koszul-regular sequence in $\bar{A}$. Letting $R=A /\left(d, r_{1}, \ldots, r_{c}\right)$, the filtered $\bar{A}$-algebra $\mathrm{F}_{\leqslant \star}^{\mathrm{conj}} \bar{\triangle}_{R / A}$ is a p-completely Koszul-regular quotient of the filtered polynomial ring

$$
R\left[\delta^{u}\left(a_{v}\right) \mid u \geqslant 0,1 \leqslant v \leqslant c\right]_{p}^{\wedge}
$$

by relations

$$
\delta^{u}\left(a_{v}\right)^{p}+p \delta^{u+1}\left(a_{v}\right)-R_{u v}
$$

where $\delta^{u}\left(a_{v}\right)$ has filtration weight $\geqslant p^{u}$. In particular, the monomials

$$
\prod_{u v} \delta^{u}\left(a_{v}\right)^{e_{u v}}
$$

for $1 \leqslant v \leqslant c, u \geqslant 0,0 \leqslant e_{u v}<p$, and $\sum_{v, u} e_{v, u} p^{u} \leqslant i$ form a $p$-completely free basis for the $R$-module $\mathrm{F}_{\leqslant i}^{\mathrm{conj}} \overline{\mathbb{}}_{R / A} \subseteq\left(A\left\{\frac{r_{1}}{d}, \ldots, \frac{r_{c}}{d}\right\}_{p}^{\wedge}\right) / d$.
Proof. We first argue that the monomials

$$
\prod_{u v} \delta^{u}\left(a_{v}\right)^{e_{u v}}
$$

form a basis for $\bar{\triangle}_{R / A}$. Indeed, Proposition 3.8 exhibits $\bar{\triangle}_{R / A}$ as a Koszul-regular quotient of

$$
R\left[\delta^{u}\left(a_{v}\right) \mid u \geqslant 0,1 \leqslant v \leqslant c\right]_{p}^{\wedge}
$$

by elements

$$
\delta^{u}\left(a_{v}\right)^{p}+p \delta^{u+1}\left(a_{v}\right)-R_{u v}
$$

where here there is no claim about the conjugate filtration. We have an ascending filtration $\mathrm{G}_{\leqslant \star}$ with $\delta^{u}\left(a_{v}\right)$ in filtration $\leqslant p^{u}$. On the associated graded ring, we are dealing with the quotient of $R\left[\delta^{u}\left(a_{v}\right) \mid u \geqslant 0,1 \leqslant\right.$ $v \leqslant c]_{p}^{\wedge}$ by relations $\delta^{u}\left(a_{v}\right)^{p}+p \delta^{u+1}\left(a_{v}\right)$. This is a free divided power algebra, which has the indicated basis. So these element form a basis before passage to the associated graded ring as well.

It remains to prove that $\mathrm{G}_{\leqslant \star}$ and the conjugate filtration $\mathrm{F}_{\leqslant \star}^{\mathrm{conj}}$ agree. Both sides satisfy base change, so it suffices to analyze the universal case of

$$
A=\mathbf{Z}_{p}\left\{d, r_{1}, \ldots, r_{c}\right\}\left[\delta(d)^{-1}\right]_{p, d}^{\wedge}
$$

Furthermore, by monoidality we can reduce to the case of a single relation, $A=\mathbf{Z}_{p}\{d, r\}$ and $R=\bar{A} / r$. We may endow $A$ with the structure of a graded prism with $r$ in degree 1 . In that case, $L_{R / \bar{A}} \simeq R(1)[1]$ since $R$ is obtained from $\bar{A}$ by quotienting by a regular element of degree 1 . So, the Hodge-Tate comparison theorem shows that

$$
\operatorname{gr}_{j}^{\mathrm{conj}} \bar{\triangle}_{R / A}=\mathrm{L} \Omega_{R / \bar{A}}^{j}[-j] \simeq R(j)
$$

We also have that $a=\frac{r}{d}$ is in degree 1 , and hence the basis element $\prod_{u} \delta^{u}(a)^{e_{u}}$ is in degree $\sum p^{u} e_{u}$. It follows that $\mathrm{gr}_{j} \mathrm{G}$ is also $R(j)$. Both $\mathrm{G}_{\leqslant j}$ and $\mathrm{F}_{\leqslant j}^{\text {conj }}$ therefore agree with the degree $\leqslant j$ part of $\bar{\triangle}_{R / A}$, and in particular agree.

Remark 3.10. Below, in Corollary 3.23 , we will see another way of seeing that the elements $\delta^{i}(a)$ must be in $\mathrm{F}_{\leqslant p^{i}}^{\mathrm{conj}} \bar{\triangle}_{R / A}$.

### 3.3 The $\delta$-ring structure on $\bigoplus \mathrm{N}^{\geqslant i} \widehat{\triangle}_{R / A}^{(1)}$

Definition 3.11. Let $(A, I)$ be a bounded prism and let $R$ be a commutative $\bar{A}$-algebra. The Frobeniustwisted prismatic cohomology of $A$, denoted by $\triangle_{R / A}^{(1)}$, is the derived $(p, I)$-completion of $\triangle_{R / A} \otimes_{A, \varphi} A$. It is equipped with an $A$-linear relative Frobenius map $\Delta_{R / A}^{(1)} \xrightarrow{\varphi_{R / A}} \Delta_{R / A}$ and there is a $\varphi_{A}$-semilinear map $w: \Delta_{R / A} \rightarrow \triangle_{R / A}^{(1)}$. The composition $w \circ \varphi_{R / A}$ is the Frobenius endomorphism of $\Delta_{R / A}^{(1)}$ and the composition $\varphi_{R / A} \circ w$ is the Frobenius endomorphism of $\Delta_{R / A}$.

Remark 3.12 (The Nygaard filtration). Let $(A, I)$ be a bounded prism and let $R$ be a commutative $\bar{A}$ algebra. There is a decreasing multiplicative exhaustive filtration $\mathrm{N}^{\geqslant \star} \Delta_{R / A}^{(1)}$, the Nygaard filtration, on $\Delta_{R / A}^{(1)}$ studied in $[10,11,8]$. The Nygaard filtration has the following properties:
(i) $\mathrm{N} \geqslant 0 \Delta_{R / A}^{(1)}=\mathrm{N}^{\geqslant-1} \triangle_{R / A}^{(1)}=\cdots=\Delta_{R / A}^{(1)}$, or equivalently $\mathrm{gr}_{\mathrm{N}}^{i} \Delta_{R / A}^{(1)}=0$ for $i<0$;
(ii) the relative Frobenius $\varphi_{R / A}: \Delta_{R / A}^{(1)} \rightarrow \Delta_{R / A}$ promotes to a natural map $\mathrm{N} \geqslant \star \Delta_{R / A}^{(1)} \rightarrow I^{\star} \Delta_{R / A}$ of filtered $\mathbf{E}_{\infty}$-rings;
(iii) the map $\operatorname{gr}_{\mathrm{N}}^{i} \Delta_{R / A}^{(1)} \rightarrow \bar{\triangle}_{R / A}\{i\}$ induced from (ii) yields an equivalence $\operatorname{gr}_{\mathrm{N}}^{i} \Delta_{R / A}^{(1)} \simeq \mathrm{F}_{\leqslant i}^{\mathrm{conj}} \bar{\triangle}_{R / A}\{i\}$ for all $i \in \mathbf{Z}$;
(iv) if $\mathrm{L}_{R / A}$ has $p$-complete Tor-amplitude in [1, 1], then the Nygaard-completed Frobenius-twisted prismatic cohomology $\widehat{\mathbb{\Delta}}_{R / A}^{(1)}$ is discrete, the natural induced relative Frobenius map $\varphi_{R / A}: \widehat{\mathbb{\Delta}}_{R / A}^{(1)} \rightarrow \Delta_{R / A}$ is injective, and $\mathrm{N} \geqslant i \widehat{\Delta}_{R / A}^{(1)}$ consists of those $x$ such that $\varphi_{R / A}(x) \in I^{i} \triangle_{R / A}$. (For the last part, in this generality, see [4, Cor. 6.13].)

Remark 3.13. Either property (iii) or property (iv) of Definition 3.12 can be used to define the filtration general [11, Thm. 15.3]. If $R$ is $p$-completely smooth over $\bar{A}$, then one lets $\mathrm{N} \geqslant \star \Delta_{R / A}^{(1)}$ be $\mathrm{L} \eta_{I} \Delta_{R / A}$, where $\mathrm{L} \eta_{I}$ denotes the décalage functor [10, Prop. 5.8], and then left Kan extends this filtration to all commutative $\bar{A}$-algebras. On the other hand, if $R$ is relatively quasiregular semiperfectoid over $\bar{A}$, then one defines the Nygaard filtration by letting $x \in \mathrm{~N}^{\geqslant i} \Delta_{R / A}^{(1)}$ if and only if $\varphi_{R / A}(x) \in I^{i} \Delta_{R / A}$. Then, this can be descended to give a definition for all relatively quasisyntomic $\bar{A}$-algebras.

For the most part, we are interested only in the Nygaard-completion of $\Delta_{R / A}^{(1)}$ when $R$ is a Koszul-regular quotient of $\bar{A}$.

Lemma 3.14. Let $(A, d)$ be a bounded, oriented prism and let $R$ be an $\bar{A}$-algebra of the form $A /\left(d, r_{1}, \ldots, r_{c}\right)$, where the images of $r_{1}, \ldots, r_{c}$ form a p-completely Koszul-regular sequence in $A / d$. By [11, Lem. 7.7], there is an equivalence

$$
\Delta_{R / A} \simeq A\left\{\frac{r_{1}}{d}, \ldots, \frac{r_{c}}{d}\right\}_{(p, d)} .
$$

The relative Frobenius

$$
\varphi_{R / A}: \Delta_{R / A}^{(1)} \rightarrow \Delta_{R / A}
$$

induces an injective map

$$
\varphi_{R / A}: \widehat{\Delta}_{R / A}^{(1)} \rightarrow \Delta_{R / A}
$$

exhibiting the Nygaard completion as the completed sub- $\delta$-ring generated by the elements $\frac{\varphi\left(r_{j}\right)}{\varphi(d)}=\varphi\left(\frac{r_{j}}{d}\right)$, i.e. as

$$
A\left\{\frac{\varphi\left(r_{1}\right)}{\varphi(d)}, \ldots, \frac{\varphi\left(r_{c}\right)}{\varphi(d)}\right\}_{(p, N)}^{\wedge} \subseteq A\left\{\frac{r_{1}}{d}, \ldots, \frac{r_{c}}{d}\right\}_{(p, d)}^{\wedge},
$$

with Nygaard filtration given by the restriction of the d-adic filtration.
Proof. As $\triangle_{R / A}$ is generated, as a $\delta$-ring over $A$, by elements $a_{j}=\frac{r_{j}}{d}$, one has that $\mathrm{H}_{0}\left(\triangle_{R / A}^{(1)}\right)$ is generated as a $\delta$-ring over $A$ by their images $a_{j} \otimes 1$. Under the relative Frobenius, these map to $\varphi\left(a_{j}\right)=\frac{\varphi\left(r_{j}\right)}{\varphi(d)}$. The Frobenius twist $\Delta_{R / A}^{(1)}$ is not necessarily discrete, but by Remark 3.12(iii) and discreteness of the associated graded terms $L \Omega_{R / \bar{A}}^{j}[-j]$ of the conjugate filtration, the Nygaard associated graded terms are discrete and embed into the $d$-adic associated graded terms. It follows that the Nygaard completion is discrete and obtained as closure of the image of $\triangle_{R / A}^{(1)}$ in $\triangle_{R / A}$ with respect to the $(p, d)$-adic topology and that the Nygaard filtration on the Nygaard completion can be obtained by restricting the $d$-adic filtration.

Remark 3.15. As suggested in Lemma 3.14, one may think of $\Delta_{R / A}^{(1)}$ as a prismatic envelope in its own right, adjoining fractions $\frac{\varphi\left(r_{j}\right)}{\varphi(d)}$. Indeed, the pushout diagram (3) at the beginning of the section base changes to an analogous pushout. The issue is that in general, both $\triangle_{R / A}^{(1)}=\triangle_{R / A} \otimes_{A, \varphi} A$ and this pushout diagram have to be interpreted in a derived way, even if $\triangle_{R / A}$ is discrete. However, in many cases, the $\varphi\left(r_{j}\right)$ also form a $p$-completely Koszul-regular sequence in $\bar{A}$, in which case the prismatic envelope is discrete, admits a description as in the preceding section, and agrees with $\triangle_{R / A}^{(1)}$.

The problem with this description is that the Nygaard filtration is rather inexplicit. We would like to find an explicit description (in terms of generators and relations) of the Nygaard filtered pieces $N \geqslant i \widehat{\Delta}_{R / A}^{(1)}$.

Example 3.16. The Nygaard filtration on prismatic envelopes is rarely complete, although it will be separated in all cases considered in this paper. For example, neither $N \geqslant{ }^{\geqslant \star} \Delta_{\left(\mathbf{Z} / p^{n}\right) / \mathbf{Z}_{p} \llbracket z_{0} \rrbracket}^{(1)}$ nor $\mathrm{N}^{\geqslant \star} \triangle_{\mathbf{Z}_{p} / \mathbf{Z}_{p} \llbracket z_{0}, z_{1} \rrbracket}^{(1)}$ is complete. Indeed, the elements $f_{j} \in \mathrm{~N} \geqslant p^{j} \widehat{\triangle}_{\left(\mathbf{Z} / p^{n}\right) / \mathbf{Z}_{p} \llbracket z_{0} \rrbracket}^{(1)}$ we construct in Proposition 3.34 lift to $\mathrm{N} \geqslant p^{j} \triangle_{\left(\mathbf{Z} / p^{n}\right) / \mathbf{Z}_{p} \llbracket z_{0} \rrbracket}^{(1)}$, but a sum such as $\sum_{j \geqslant 0} f_{j}$ exists in the Nygaard-completion, but does not exist before Nygaard-completion.

Construction 3.17. Let $(A, d)$ be an oriented prism and let $R$ be a commutative $\bar{A}$-algebra with $\mathrm{L}_{R / \bar{A}}$ having $p$-complete Tor-amplitude in $[1,1]$. Consider the graded ring $\bigoplus_{i \geqslant 0} \mathrm{~N} \geqslant i \widehat{\triangle}_{R / A}^{(1)}$. Define functions

$$
\begin{gathered}
\widetilde{\varphi}_{i}: \mathrm{N}^{\geqslant i} \widehat{\Delta}_{R / A}^{(1)} \rightarrow \mathrm{N}^{\geqslant p i} \widehat{\Delta}_{R / A}^{(1)} \quad \text { by } \quad \widetilde{\varphi}_{i}(x)=\frac{\varphi(x)}{\varphi(d)^{2}} d^{p i} \\
\widetilde{\delta}_{i}: \mathrm{N}^{\geqslant i} \widehat{\triangle}_{R / A}^{(1)} \rightarrow \mathrm{N}^{\geqslant p i} \widehat{\triangle}_{R / A}^{(1)} \quad \text { by } \quad \widetilde{\delta}_{i}(x)=\delta(x)-\delta\left(d^{i}\right) \frac{\varphi(x)}{\varphi(d)^{i}} .
\end{gathered}
$$

Using part (iv) of Remark 3.12, we also have the $A$-linear $d$-divided relative Frobenius maps

$$
\varphi_{i, R / A}: \mathrm{N}^{\geqslant i} \widehat{\triangle}_{R / A}^{(1)} \rightarrow \triangle_{R / A} \quad \text { defined by } \quad \varphi_{i, R / A}(x)=\frac{\varphi_{R / A}(x)}{d^{i}}
$$

and the $\varphi(d)$-divided Frobenius maps

$$
\varphi_{i}: \mathrm{N}^{\geqslant i} \widehat{\triangle}_{R / A}^{(1)} \rightarrow \widehat{\mathbb{}}_{R / A}^{(1)} \quad \text { defined by } \quad \varphi_{i}(x)=\frac{\varphi(x)}{\varphi(d)^{i}} .
$$

Notation 3.18. We will write $\widetilde{\delta}=\bigoplus_{i \geqslant 0} \widetilde{\delta}_{i}$ and $\widetilde{\varphi}=\bigoplus_{i \geqslant 0} \widetilde{\varphi}_{i}$ as graded functions on $\bigoplus_{i \geqslant 0} \mathrm{~N} \geqslant i \widehat{\Delta}_{R / A}^{(1)}$.
Proposition 3.19 (The graded $\delta$-ring structure). Let $(A, d)$ be a bounded oriented prism and let $R$ be a commutative $\bar{A}$-algebra with $\mathrm{L}_{R / \bar{A}}$ having p-complete Tor-amplitude in $[1,1]$. The operation $\widetilde{\delta}$ makes $\bigoplus_{\star \geqslant 0} \mathrm{~N} \geqslant \star \widehat{\Delta}_{R / A}^{(1)}$ into a graded $\delta$-ring with graded Frobenius morphism $\widetilde{\varphi}$; the relative divided Frobenius map

$$
\bigoplus_{\star \geqslant 0} \mathrm{~N}^{\geqslant *} \widehat{\mathbb{}}_{R / A}^{(1)} \xrightarrow{\oplus \varphi_{i, R / A}} \mathbb{\Delta}_{R / A}
$$

is a $\delta$-ring morphism.
Proof. Let $x \in \mathrm{~N}^{\geqslant i} \widehat{\triangle}_{R / A}^{(1)}$. While $\widetilde{\varphi}_{i}(x) \in \mathrm{N} \geqslant p i \widehat{\triangle}_{R / A}^{(1)}$ follows because $d^{p i} \in \mathrm{~N}^{\geqslant p i} \widehat{\triangle}_{R / A}^{(1)}$, it is less obvious that $\widetilde{\delta}_{i}$ preserves the gradings in the claimed way. Nevertheless,

$$
x^{p}+p \widetilde{\delta}_{i}(x)=x^{p}+p\left(\delta(x)-\delta\left(d^{i}\right) \frac{\varphi(x)}{\varphi(d)^{i}}\right)=\frac{\left(x^{p}+p \delta(x)\right) \varphi(d)^{i}-p \delta\left(d^{i}\right) \varphi(x)}{\varphi(d)^{i}}=\frac{\varphi(x)}{\varphi(d)^{2}} d^{p i}=\widetilde{\varphi}_{i}(x) .
$$

so that $p \widetilde{\delta}_{i}(x)$ is in weight pi. By reduction to a universal case using base change, we can assume that the Nygaard-filtered pieces $\mathrm{N} \geqslant i \widehat{\triangle}_{R / A}^{(1)}$ are $p$-torsion free and hence that $\widetilde{\delta}_{i}(x)$ is in weight $p i$, as desired. As $\widetilde{\varphi}_{i}$ is a graded ring endomorphism by definition, it also follows that it is a lift of Frobenius with associated $\delta$-ring structure given by $\widetilde{\delta}$.

Again, using reduction to a $p$-torsion free case, to check that the relative divided Frobenius maps $\varphi_{i, R / A}$ assemble into a $\delta$-ring morphism, it is enough to check that they commute with the Frobenius endomorphisms. But, e have

$$
\varphi_{p i, R / A}\left(\widetilde{\varphi}_{i}(x)\right)=\varphi_{R / A}\left(\frac{\varphi(x)}{\varphi(d)^{2}} d^{p i}\right) \frac{1}{d^{p i}}=\frac{\varphi_{R / A}(\varphi(x))}{\varphi(d)^{i}}=\varphi\left(\frac{\varphi_{R / A}(x)}{d^{i}}\right)=\varphi\left(\varphi_{i, R / A}(x)\right)
$$

using $A$-linearity and $\varphi(d)$-torsion freeness of $\Delta_{R / A}$ to commute $d^{p i}$ and $\varphi(d)^{i}$ through $\varphi_{R / A}$ and using that $\varphi_{R / A}$ is a map of $\delta$-rings to say that $\varphi\left(\varphi_{R / A}(x)\right)=\varphi_{R / A}(\varphi(x))$.
Warning 3.20. In the oriented case, the $\delta$-ring structure $\widetilde{\delta}$ on $\bigoplus_{\star \geqslant 0} \mathrm{~N} \geqslant \star \widehat{\Delta}_{R / A}^{(1)}$ does not descend to a filtered $\delta$-ring structure on $\mathrm{N} \geqslant \star \widehat{\triangle}_{R / A}^{(1)}$. Indeed, if it did, in the case of $\widehat{\triangle}_{\mathbf{F}_{p} / \mathbf{Z}_{p}}$, one would obtain on $\mathrm{gr}_{N}^{0} \widehat{\triangle}_{\mathbf{F}_{p} / \mathbf{Z}_{p}} \simeq \mathbf{F}_{p}$ a $\delta$-ring structure, which is absurd. This is explained by the fact that $\widetilde{\delta}$ does not commute with the transition $\operatorname{maps} \mathrm{N} \geqslant i+1 \widehat{\mathbb{}}_{R / A}^{(1)} \rightarrow \mathrm{N}^{\geqslant i} \widehat{\triangle}_{R / A}^{(1)}$.

### 3.4 Generators for the Nygaard filtration

We are now ready to define the generators for the Nygaard filtration.
Construction 3.21 (The $f_{u, v}$ generators). Fix a bounded, oriented prism $(A, d)$ and a sequence of elements $r_{1}, \ldots, r_{c} \in A$ that define a $p$-completely Koszul-regular sequence in $\bar{A}$; let $R=A /\left(d, r_{1}, \ldots, r_{c}\right)$. We let $\widetilde{r}_{v}$ denote the image of $r_{v}$ in $\mathrm{N} \geqslant 1 \widehat{\triangle}_{R / A}^{(1)}$ under

$$
\mathrm{N}^{\geqslant 1} \widehat{\triangle}_{R / A}^{(1)} \subseteq \widehat{\triangle}_{R / A}^{(1)} \cong\left(\triangle_{R / A} \otimes_{A, \varphi} A\right)_{p, \mathrm{~N}}^{\wedge}
$$

For $1 \leqslant v \leqslant c$ and $u \geqslant 0$, we define $f_{u, v} \in \mathrm{~N} \geqslant p^{u} \widehat{\Delta}_{R / A}^{(1)}$ by

$$
f_{u, v}=\widetilde{\delta}^{u}\left(r_{v}\right)
$$

Additionally, we let

$$
a_{v}=\varphi_{1, R / A}\left(f_{0, v}\right) \in \mathbb{\mathbb { A }}_{R / A}
$$

We first remark that there is no conflict in notation between the $a_{v}$ from Construction 3.21 and those from Proposition 3.8.

Lemma 3.22. If $(A, d)$ is a bounded, oriented prism and $r_{1}, \ldots, r_{c}$ is a sequence of elements whose image in $\bar{A}$ is p-completely Koszul-regular, then $a_{v} \in \triangle_{R / A}$ satisfies $d a_{v}=r_{v}$ for $1 \leqslant v \leqslant c$. Moreover, the induced map

$$
A\left\{\frac{r_{1}}{d}, \ldots, \frac{r_{c}}{d}\right\}_{(p, d)}^{\wedge} \rightarrow \Delta_{R / A}
$$

is an equivalence.
Proof. By definition, $a_{v}=\varphi_{1, R / A}\left(f_{0, v}\right)=\frac{\varphi_{R / A}\left(\widetilde{r}_{v}\right)}{d}$, so $d a_{v}=\varphi_{R / A}\left(\widetilde{r}_{v}\right)$. But, since $\varphi_{R / A}$ is $A$-linear, $\varphi_{R / A}\left(\widetilde{r}_{v}\right)=r_{v}$, so we have that $d a_{v}=r_{v}$. Now, there is an induced map

$$
A\left\{\frac{r_{1}}{d}, \ldots, \frac{r_{c}}{d}\right\}_{(p, d)}^{\wedge} \rightarrow \mathbb{\triangle}_{R / A}
$$

by definition of the prismatic envelope. But, this map is the map arising in the proof of the fact that the prismatic envelope of an lci quotient computes the prismatic cohomology in [11, Ex. 7.9]; in particular, it is an equivalence.

Corollary 3.23. If $(A, d)$ is a bounded, oriented prism and $r_{1}, \ldots, r_{c}$ is a sequence of elements whose image in $\bar{A}$ is p-completely Koszul-regular, then for every $1 \leqslant v \leqslant c$ and every $u \geqslant 0$, one has $\varphi_{p^{u}, R / A}\left(f_{u, v}\right)=\delta^{u}\left(a_{v}\right)$ and the image of $\delta^{u} a_{v}$ in $\bar{\triangle}_{R / A}$ is in $\mathrm{F}_{\leqslant p^{u}}^{\mathrm{conj}} \bar{\triangle}_{R / A}$.
Proof. The first statement follows by the compatibility of $\widetilde{\delta}$ and $\delta$ under $\varphi_{\star, R / A}$ established in Proposition 3.19. The second statement follows from the fact that the relative Frobenius induces an equivalence $\operatorname{gr}_{\mathrm{N}}^{p^{u}} \widehat{\triangle}_{R / A}^{(1)} \simeq$ $\mathrm{F}_{p^{u}}^{\mathrm{conj}} \overline{\mathbb{}}_{R / A}$ (see for example [8, Rem. 5.1.2]).

Lemma 3.24 (Relations for the $\left.f_{u, v}\right)$. Let $\widetilde{d} \in \mathrm{~N}^{\geqslant} \widehat{\mathbb{}}_{R / A}^{(1)}$ be d, regarded as element of Nygaard filtration $\geqslant 1$. The elements $f_{u, v}$ satisfy relations

$$
f_{u, v}^{p}=\left(-p+\lambda_{u} d^{p^{u+1}}\right) f_{u+1, v}+{\widetilde{d^{p}}}^{u+1} R_{u, v}^{\prime}
$$

in $\mathrm{N} \geqslant p^{u} \widehat{\Delta}_{R / A}^{(1)}$, where $\lambda_{u}$ is given by $\lambda_{0}=-\frac{1}{\delta(d)}$ and

$$
\lambda_{u+1}=\frac{\lambda_{u}^{p}}{1-\delta\left(d^{p^{u+1}} \lambda_{u}\right)}
$$

and the $R_{u, v}^{\prime} \in \mathrm{N} \geqslant 0 \widehat{\triangle}_{R / A}^{(1)}$ are given by $R_{0, v}^{\prime}=\frac{\delta\left(r_{v}\right)}{\delta(d)}$ and

$$
R_{u+1, v}^{\prime}=\frac{1}{1-\delta\left(d^{p^{u+1}} \lambda_{u}\right)}\left(\delta\left(R_{u, v}^{\prime}\right)+w_{1}\left(\lambda_{u} f_{u+1, v}, R_{u, v}^{\prime}\right)\right)
$$

Remark 3.25. Note that in the statement of Lemma 3.24, $\delta$ does not preserve the Nygaard filtration in any way.
Proof of Lemma 3.24. Applying Lemma 3.6 to the graded $\delta$-ring $\bigoplus_{\star \geqslant 0} \mathrm{~N} \geqslant \star \widehat{\Delta}_{R / A}^{(1)}$ and the relation $d f_{0, v}=\tilde{d r}$, we obtain relations

$$
f_{u, v}^{p}=\left(-p+\lambda_{u} d^{p^{u+1}}\right) f_{u+1, v}+R_{u, v}
$$

using $\widetilde{\delta}(\widetilde{d})=0$, with $R_{0, v}=\frac{\widetilde{\delta}\left(\widetilde{d} r_{v}\right)}{\delta(d)}=\widetilde{d}^{p} R_{0, v}^{\prime}$. Now $R_{u, v}$ satisfies the recursion

$$
R_{u+1, v}=\frac{1}{1-\delta\left(d^{p^{u+1} \lambda_{u}}\right)}\left(\widetilde{\delta}\left(R_{u, v}\right)+w_{1}\left(d^{p^{u+1}} \lambda_{u} f_{u+1, v}, R_{u, v}\right)\right.
$$

We may rewrite $d^{p^{u+1}} f_{u+1, v}$ as $\widetilde{d}^{p+1} \cdot f_{u+1, v}$ in $\mathrm{N} \geqslant p^{u+1} \widehat{\Delta}_{R / A}^{(1)}$. It inductively follows that

$$
R_{u+1, v}=\widetilde{d}^{p^{u+1}} R_{u+1, v}^{\prime}
$$

proving the claimed relation.
Lemma 3.26 (Structure maps on the $f_{u, v}$ ). The divided Frobenius and $\delta$-structure maps are determined on the elements $f_{u, v}$ by
(1) $\varphi_{p^{u}}\left(f_{u, v}\right)=\lambda_{u} f_{u+1, v}+R_{u, v}^{\prime}$,
(2) $\varphi\left(f_{u, v}\right)=\varphi(d)^{p^{u}} \cdot\left(\lambda_{u} f_{u+1, v}+R_{u, v}^{\prime}\right)$, and
(3) $\delta\left(f_{u, v}\right)=\left(1+\delta\left(d^{p^{u}}\right) \lambda_{u}\right) f_{u+1, v}+\delta\left(d^{p^{u}}\right) R_{u, v}^{\prime}$

Proof. We have

$$
\widetilde{\varphi}\left(f_{u, v}\right)=f_{u, v}^{p}+p f_{u+1, v}=\lambda_{u} d^{p^{u+1}} f_{u+1, v}+\widetilde{d}^{p^{u+1}} R_{u, v}^{\prime}
$$

Using $\widetilde{\varphi}\left(f_{u, v}\right)=\widetilde{d^{p}}{ }^{u+1} \varphi_{p^{u}}\left(f_{u, v}\right)$ and rewriting $d^{p^{u+1}} f_{u+1, v}=\widetilde{d}^{p^{u+1}} f_{u+1, v}$, this implies

$$
\varphi_{p^{u}}\left(f_{u, v}\right)=\lambda_{u} f_{u+1, v}+R_{u, v}^{\prime}
$$

since $\tilde{d}$ acts as nonzerodivisor on the Nygaard filtration: indeed, on the associated graded pieces of the Nygaard filtration, $\widetilde{d}$ fits into a commutative diagram

where the last map has discrete cofiber $\widehat{\mathrm{L}}_{R / \bar{A}}^{j}[-j]$ by assumption. Since $\varphi\left(f_{u, v}\right)=\varphi(d)^{p^{u}} \varphi_{p^{u}}\left(f_{u, v}\right)$, the second claim follows.

Finally, observe that

$$
f_{u, v}^{p}=\left(-p+\lambda_{u} d^{p^{u+1}}\right) f_{u+1, v}+d^{p^{u+1}} R_{u, v}^{\prime}
$$

and, since $\varphi\left(d^{p^{u}}\right)=d^{p^{u+1}}+p \delta\left(d^{p^{u}}\right)$,

$$
\varphi\left(f_{u, v}\right)=\left(d^{p^{u+1}}+p \delta\left(d^{p^{u}}\right)\right) \cdot\left(\lambda_{u} f_{u+1, v}+R_{u, v}^{\prime}\right)
$$

taking the difference,

$$
\varphi\left(f_{u, v}\right)-f_{u, v}^{p}=p \delta\left(f_{u, v}\right)=p\left(1+\delta\left(d^{p^{u}}\right) \lambda_{u}\right) f_{u+1, v}+p \delta\left(d^{p^{u}}\right) R_{u, v}^{\prime}
$$

which we may divide by $p$ to prove the last claim, since it suffices to prove these relations in the universal case, where everything is $p$-torsion free.
Remark 3.27 (Translating between the $f_{u, v}$ and $\delta^{u}\left(a_{v}\right)$ ). Since the relative divided Frobenius satisfies $\varphi_{p^{u}, R / A}\left(f_{u, v}\right)=\delta^{u}\left(a_{v}\right)$, part (1) of Lemma 3.26 implies that

$$
w\left(\delta^{u}\left(a_{v}\right)\right)=\lambda_{u} f_{u+1, v}+R_{u, v}^{\prime}
$$

expressing the image of our generators of $\triangle_{R / A}$ in the Frobenius twist $\widehat{\Delta}_{R / A}^{(1)}$ in terms of the $f_{u, v}$. As the leading coefficient here is a unit, this in fact provides a way to translate between the $f_{u, v}$ and the $\delta^{u}\left(a_{v}\right)$. One may use this to obtain a generators-and-relations description of $\Delta_{R / A}^{(1)}$ in terms of the $f_{u, v}$ and the above relations. We prove this below only for the Nygaard completion $N \geqslant * \widehat{\Delta}_{R / A}^{(1)}$ in a different way and will not need to directly translate between these two sets of generators.

We now want to express the fact that, as a filtered ring, $\mathrm{N} \geqslant \star \widehat{\Delta}_{R / A}^{(1)}$ is generated by the $f_{u, v}$ subject to the relations from Lemma 3.24. The problem is that the $R_{u, v}^{\prime}$ are only defined as elements of $\mathrm{N} \geqslant \star \widehat{\Delta}_{R / A}^{(1)}$ rather than abstract polynomials in the $f_{u, v}$, and since the recursion involves the $\delta$-ring structure on $\widehat{\Delta}_{R / A}^{(1)}$, it is not immediately obvious how to lift them to polynomials. The following construction accomplishes that.
Construction 3.28. On the polynomial ring $A\left[f_{u, v} \mid u \geqslant 0,1 \leqslant v \leqslant c\right]_{p, d}^{\wedge}$, we introduce a $\delta$-ring structure and elements $R_{u, v}^{\prime}$ through $R_{0, v}^{\prime}=\frac{\delta\left(r_{v}\right)}{\delta(d)}$ and the mutual recursions

$$
\begin{gathered}
\delta\left(f_{u, v}\right)=\left(1+\delta\left(d^{p^{u}}\right) \lambda_{u}\right) f_{u+1, v}+\delta\left(d^{p^{u}}\right) R_{u, v}^{\prime} \\
R_{u+1, v}^{\prime}=\frac{1}{1-\delta\left(d^{p^{u+1}} \lambda_{u}\right)}\left(\delta\left(R_{u, v}^{\prime}\right)+w_{1}\left(\lambda_{u} f_{u+1, v}, R_{u, v}^{\prime}\right)\right)
\end{gathered}
$$

This works since inductively, $R_{u, v}^{\prime}$ is a polynomial in $f_{0, v}, \ldots, f_{u, v}$, and $\delta\left(f_{u, v}\right)$ is a polynomial in $f_{0, v}, \ldots, f_{u+1, v}$.
Also note that with respect to the ascending filtration $\mathrm{G}_{\leqslant \star} A\left[f_{u, v}\right]_{p, d}^{\wedge}$ where $f_{u, v}$ has filtration $\leqslant p^{u}$, one inductively sees that $R_{u, v} \in \mathrm{G}_{<p^{u+1}} A\left[f_{u, v}\right]_{p, d}^{\wedge}$ and $\delta\left(\mathrm{G}_{\leqslant \star} A\left[f_{u, v}\right]_{p, d}^{\wedge}\right) \subseteq \mathrm{G}_{\leqslant p \star} A\left[f_{u, v}\right]_{p, d}^{\wedge}$. In particular, $R_{u, v}^{\prime}$ involves $f_{u, v}$ with exponents strictly smaller than $p$.

Finally, note that the map $A\left[f_{u, v}\right]_{p, d}^{\wedge} \rightarrow \widehat{\triangle}_{R / A}^{(1)}$ is a map of $\delta$-rings and takes $R_{u, v}^{\prime}$ to the element of the same name.
Remark 3.29. If $\delta(r)=0$, observe that the $R_{u}^{\prime}$ are all inductively zero.
Proposition 3.30. If $(A, d)$ is a bounded, oriented prism and $r_{1}, \ldots, r_{c}$ is a sequence of elements whose image in $\bar{A}$ is p-completely Koszul-regular, then, as a graded commutative $R$-algebra, $\bigoplus_{\star \geqslant 0} \operatorname{gr}_{\mathrm{N}}^{\star} \widehat{\Delta}_{R / A}^{(1)}$ is a p-completely Koszul-regular quotient of the $p$-complete graded polynomial ring $R\left[\widetilde{d}, f_{u, v} \mid u \geqslant 0,1 \leqslant v \leqslant c\right]_{p}^{\wedge}$, where $\widetilde{d}$ is in weight 1 and corresponds to $d \in \operatorname{gr}_{\mathrm{N}}^{1} \widehat{\triangle}_{R / A}^{(1)}$ and $f_{u, v}$ is in weight $p^{u}$, by the relations

$$
f_{u, v}^{p}=\left(-p+\lambda_{u} d^{p^{u+1}}\right) f_{u+1, v}+\widetilde{d}^{p^{u+1}} R_{u, v}^{\prime}
$$

As a graded $R$-module, $\bigoplus_{\star \geqslant 0} \operatorname{gr}_{\mathrm{N}}^{\star} \widehat{\mathbb{}}_{R / A}^{(1)}$ is $p$-completely free on monomials $\widetilde{d}^{k} \prod f_{u, v}^{e_{u, v}} \in \operatorname{gr}_{\mathrm{N}}^{k+\sum p^{u} e_{u, v}} \widehat{\Delta}_{R / A}$ with $e_{u, v}<p$.

Proof. Recall that we have commutative diagrams

so $\widetilde{d}$ acts injectively on $\operatorname{gr}_{\mathrm{N}}^{\star} \widehat{\widehat{ }}_{R / A}^{(1)}$. The relations hold by Lemma 3.24. To check that they form a $p$-completely regular sequence, it suffices to know that they do so modulo $\widetilde{d}$. This reduces to the claim that the elements $f_{u, v}^{p}+p f_{u+1, v}$ for $u \geqslant 0$ and $1 \leqslant v \leqslant c$ form a $p$-completely regular sequence in $R\left[f_{u, v} \mid u \geqslant 0,1 \leqslant v \leqslant c\right]_{p}^{\wedge}$, which is clear. This also shows that the monomials $\widetilde{d}^{k} \prod f_{u, v}^{e_{u, v}}$ form a basis of the quotient of $R\left[\widetilde{d}, f_{u, v} \mid u \geqslant\right.$ $0,1 \leqslant v \leqslant c]_{p}^{\wedge}$ by the indicated relations. The divided relative Frobenius $\varphi_{i, R / A}: \operatorname{gr}_{\mathrm{N}}^{i} \widehat{\triangle}_{R / A}^{(1)} \xrightarrow{\simeq} \mathrm{F}_{\leqslant i}^{\text {conj }} \bar{\Delta}_{R / A}$ takes the $\widetilde{d}^{i-\sum p^{u} e_{u, v}} \prod f_{u, v}^{e_{u, v}}$ to $\prod \delta^{u}\left(a_{v}\right)^{e_{u, v}}$, so $\operatorname{gr}_{\mathrm{N}}^{\star} \widehat{\triangle}_{R / A}^{(1)}$ is also free on the same set of monomials.

Recall that in our convention is that in $\mathrm{N} \geqslant \star \widehat{\mathbb{}}_{R / A}^{(1)}$ the element $\tau$ denotes 1 , but viewed as being in $\mathrm{N} \geqslant-1 \widehat{\mathbb{}}_{R / A}^{(1)}$. In the corollary below, $\tau f_{0, v}$ is then in $\mathrm{N} \geqslant 0 \widehat{\triangle}_{R / A}^{(1)}$.

Corollary 3.31. If $(A, d)$ is a bounded, oriented prism and $r_{1}, \ldots, r_{c}$ is a sequence of elements whose image in $\bar{A}$ is $p$-completely Koszul-regular with quotient $R$, then, as a complete filtered commutative $d^{\star} A \cong$ $\mathrm{N} \geqslant \star \widehat{\triangle}_{\bar{A} / A}^{(1)}$-algebra, $\mathrm{N} \geqslant \star \widehat{\Delta}_{R / A}^{(1)}$ is a p-completely Koszul-regular quotient of the p-complete complete filtered polynomial ring $d^{\star} A\left[f_{u, v} \mid u \geqslant 0,1 \leqslant v \leqslant c\right]_{p, \mathrm{~N}}^{\wedge}$, where $f_{u, v}$ is in weight $p^{u}$, by relations $\tau f_{0, v}-r_{v}$ of weight 0 and the relations

$$
f_{u, v}^{p}=\left(-p+\lambda_{u} d^{p^{u+1}}\right) f_{u+1, v}+{\widetilde{d^{p}}}^{u+1} R_{u, v}^{\prime}
$$

$\delta_{d, p^{u-1}} \cdots \delta_{d, 1}\left(d f_{0, v}-\widetilde{d} r_{v}\right)$ for $u \geqslant 1$ of weight $p^{u}$.
Proof. There is a filtered map $d^{\star} A\left[f_{u v} \mid u \geqslant 0,1 \leqslant v \leqslant c\right]_{p, \mathrm{~N}}^{\wedge} \rightarrow \mathrm{N} \geqslant \star \widehat{\Delta}_{R / A}^{(1)}$ taking the elements $f_{u v}$ to the corresponding elements of $\mathrm{N} \geqslant \star \widehat{\Delta}_{R / A}^{(1)}$ defined in Construction 3.21. By construction, $\tau f_{0 v}$ maps to $r_{v}$ in $\mathrm{N} \geqslant \star \widehat{\triangle}_{R / A}^{(1)}$, so it follows that the map factors through the quotient by the indicated relations. We may check whether that map is an equivalence after passing to the associated graded ring, which corresponds to reducing $\bmod \tau$. This turns the $\tau f_{0 v}-r_{v}$ into $-r_{v}$, which reduces the claim to Proposition 3.30.

Remark 3.32. Corollary 3.31 is almost expressing $\bigoplus \mathrm{N}^{\geqslant} \widehat{\Delta}_{R / A}^{(1)}$ as the prismatic envelope $A[\widetilde{d}]\left\{\left.\frac{\tilde{d} r_{v}}{d} \right\rvert\, 1 \leqslant\right.$ $v \leqslant c\}$. However, this is just a graded and not a filtered object. One might want to take a prismatic envelope in filtered objects, but the problem is that $\widetilde{\delta}$ is not compatible with $\tau$. (See Warning 3.20.) One valid description along those lines is

$$
\bigoplus_{i \in \mathbf{Z}} \mathrm{~N}^{\geqslant i} \widehat{\triangle}_{R / A}^{(1)} \cong \frac{\left(A[\widetilde{d}]\left\{\frac{\widetilde{d} r_{v}}{d}\right\}\right)[\tau]}{\left(\tau \widetilde{d}-d, \tau \frac{\widetilde{d} r_{v}}{d}-r_{v}\right)}
$$

which however is not a derived quotient, as the relations $\tau \widetilde{d}-d$ and $\tau \frac{\widetilde{d} r_{v}}{d}-r_{v}$ are redundant with $d \cdot \frac{\widetilde{d} r_{v}}{d}-\widetilde{d} r_{v}$.

### 3.5 The F-filtration on prismatic envelopes

We now specialize to the following situation. We take as our prism $A$ a multivariable Breuil-Kisin prism $A=W(k) \llbracket z_{0}, \ldots, z_{s} \rrbracket$ with Eisenstein polynomial $E\left(z_{0}\right)$. We consider this as a filtered $\delta$-ring with $z_{0}, \ldots, z_{s}$ in filtration weight 1 . We consider $R=\mathcal{O}_{K}$ or $\mathcal{O}_{K} / \varpi^{n}$ as a filtered commutative $A$-algebra by letting $z_{0}, \ldots, z_{s}$ map to $\varpi$. As explained in [4], in this case the prismatic cohomology $\triangle_{R / A}$ obtains a secondary filtrations compatible with all structure, which we will denote everywhere by $\mathrm{F}^{\star}$. In particular, we have the F-filtrations $\mathrm{F}^{\star} \triangle_{R / A}$ and $\mathrm{F}^{\star} \mathrm{N}^{[a, b]} \widehat{\triangle}_{R / A}^{(1)}$.

Proposition 3.33. Let $\mathcal{O}_{K}$ be a discrete valuation ring with residue field $k$ perfect of characteristic $p$ and with uniformizer $\varpi$. Let $A=W(k) \llbracket z_{0}, \ldots, z_{s} \rrbracket$ be the filtered $\delta$-ring defined by letting each of $z_{0}, \ldots, z_{s}$ have weight 1 and letting $\delta\left(z_{0}\right)=\cdots=\delta\left(z_{s}\right)=0$. We view $\mathcal{O}_{K}$ and $\mathcal{O}_{K} / \varpi^{n}$ as $A$-algebras by letting $z_{0}, \ldots, z_{s}$ map to $\varpi$.
(1) For $R=\mathcal{O}_{K}$, we have elements $\delta^{u}\left(b_{1}\right), \ldots, \delta^{u}\left(b_{s}\right) \in \mathrm{F} \geqslant p^{u} \Delta_{R / A}$ for $u \geqslant 0$ corresponding to the relations $z_{1}-z_{0}, \ldots, z_{s}-z_{0} . A W(k)$-basis for $\mathrm{F}^{[a, b]} \triangle_{R / A}$ is given by the monomials

$$
z_{0}^{k} \prod_{u \geqslant 0, v \in[1, s]} \delta^{u}\left(b_{v}\right)^{e_{u v}}
$$

with $0 \leqslant e_{u v}<p$ for all $u, v$ and $k+\sum p^{u} e_{u v} \in[a, b]$.
(2) For $R=\mathcal{O}_{K} / \varpi^{n}$, in addition to $\delta^{u}\left(b_{1}\right), \cdots, \delta^{u}\left(b_{s}\right)$ above, there are elements $\delta^{u}(a) \in \mathrm{F} \geqslant n p^{u} \mathbb{\Delta}_{R / A}$ for $u \geqslant 0$ corresponding to the relation $z^{n}=0$. A W $(k)$-basis for $\mathrm{F}^{[a, b]} \triangle_{R / A}$ is given by the elements

$$
z_{0}^{k} \prod_{u \geqslant 0} \delta^{u}(a)^{e_{u}} \prod_{u \geqslant 0, v \in[1, s]} \delta^{u}\left(b_{v}\right)^{e_{u v}}
$$

with (i) $0 \leqslant e_{u}<p$ for all $u \geqslant 0$, (ii) $0 \leqslant e_{u v}<p$ for all $u$, $v$, (iii) $k<n$, and (iv) $k+n \sum_{u \geqslant 0} p^{u} e_{u}+$ $\sum_{v \in[1, s]} p^{u} e_{u v} \in[a, b]$.
Proof. We give the proof of (1). In this case, Proposition 3.8 presents $\mathbb{M}_{R / W(k) \llbracket z_{0}, \ldots, z_{s} \rrbracket}$ as the prismatic envelope

$$
W(k) \llbracket z_{0}, \ldots, z_{s} \rrbracket\left\{\frac{z_{1}-z_{0}}{E\left(z_{0}\right)}, \ldots, \frac{z_{s}-z_{0}}{E\left(z_{0}\right)}\right\}_{p, E\left(z_{0}\right)}^{\wedge}
$$

We let $b_{v}=\frac{z_{v}-z_{0}}{E\left(z_{0}\right)}$, which has weight 1 and hence the $\delta$-iterates $\delta^{u}\left(b_{v}\right)$ have weight $p^{u}$. By Proposition 3.9, the monomials with $k=0$ give $p$-complete generators of $\bar{\Delta}_{R / W(k) \llbracket z_{0}, \ldots, z_{s} \rrbracket}$ as a module over $R \cong W(k) \llbracket z_{0} \rrbracket / E\left(z_{0}\right)$. It follows that the monomials with $k=0$ give $\left(p, E\left(z_{0}\right)\right)$-complete generators of the prismatic cohomology as $W(k) \llbracket z_{0} \rrbracket$-module. Thus, the monomials where $k$ is now allowed to vary give an F -complete basis for the prismatic envelope as a $p$-complete $W(k)$-module. It remains to argue that each monomial is in the given weight and not in a possibly higher weight. Equivalently, we must check that the given elements form a basis for the F-associated graded ring, which follows from [4, Prop. 10.41]. The proof of (2) proceeds analogously.

Proposition 3.34. Let $\mathcal{O}_{K}$ be a discrete valuation ring with residue field $k$ perfect of characteristic $p$ and with uniformizer $\varpi$. Let $A=W(k) \llbracket z_{0}, \ldots, z_{s} \rrbracket$ be the filtered $\delta$-ring defined by letting each of $z_{0}, \ldots, z_{s}$ have weight 1 and letting $\delta\left(z_{0}\right)=\cdots=\delta\left(z_{s}\right)=0$. We view $\mathcal{O}_{K}$ and $\mathcal{O}_{K} / \varpi^{n}$ as $A$-algebras by letting $z_{0}, \ldots, z_{s}$ map to $\varpi$.
(1) For $R=\mathcal{O}_{K}$, we have elements $g_{u, 1}, \ldots, g_{u, s} \in \mathrm{~F} \geqslant p^{u} \mathrm{~N}^{\geqslant p^{u}} \widehat{\Delta}_{R / A}^{(1)}$ for $u \geqslant 0$ corresponding to the relations $z_{1}-z_{0}, \ldots, z_{s}-z_{0} . A W(k)$-basis for $\mathrm{F}^{[a, b]} \mathrm{N} \geqslant i \widehat{\triangle}_{R / A}^{(1)}$ is given by the monomials

$$
\widetilde{d}^{j} z_{0}^{k} \prod_{u \geqslant 0, v \in[1, s]} g_{u, v}^{e_{u, v}}
$$

with $0 \leqslant e_{u, v}<p$ for all $u, v, j+\sum p^{u} e_{u, v}=i$ or $j=0$ and $\sum p^{u} e_{u, v} \geqslant i$, and $k+\sum p^{u} e_{u, v} \in[a, b]$.
(2) For $R=\mathcal{O}_{K} / \varpi^{n}$, in addition to $g_{u, 1}, \ldots, g_{u, s}$ above, there are elements $f_{u} \in \mathrm{~F} \geqslant n p^{u} \mathrm{~N} \geqslant p^{u} \widehat{\mathbb{}}_{R / A}^{(1)}$ for $u \geqslant 0$ corresponding to the relation $z^{n}=0$. A W $(k)$-basis for $\mathrm{F}^{[a, b]} \mathrm{N} \geqslant i \widehat{\Delta}_{R / A}^{(1)}$ is given by the elements

$$
\widetilde{d}^{j} z_{0}^{k} \prod_{u \geqslant 0} f_{u}^{e_{u}} \prod_{u \geqslant 0, v \in[1, s]} g_{u, v}^{e_{u, v}}
$$

such that (i) $0 \leqslant e_{u}<p$ for all $u \geqslant 0$, (ii) $0 \leqslant e_{u, v}<p$ for all $u \geqslant 0$ and $1 \leqslant v \leqslant s$ (iii) $k<n$, (iv) $j+\sum p^{u} e_{u}+\sum p^{u} e_{u, v}=i$ or $j=0$ and $\sum p^{u} e_{u}+\sum p^{u} e_{u, v} \geqslant i$, and (v) $k+n \sum_{u \geqslant 0} p^{u} e_{u}+$ $\sum_{v \in[1, s]} p^{u} e_{u, v} \in[a, b]$.

Proof. We prove the second statement, the first statement is easier and completely analogous. It suffices to check that those elements form a basis for the F-associated graded, i.e. by crystalline degeneration we may reduce to the case of $R=k[z] / z^{n}$. Now Proposition 3.30 tells us that the elements $\widetilde{d}^{j} \prod f_{u, v}^{e_{u, v}}$ with $e_{u, v}<p$ and $j+\sum p^{u} e_{u, v} \geqslant i$ form a $k[z] / z^{n}$-basis for the Nygaard-associated graded $\bigoplus_{i^{\prime} \geqslant i} \operatorname{gr}_{\mathrm{N}}^{i_{N}^{\prime}} \widehat{\mathbb{}}_{R / A}^{(1)}$. So, the elements $\widetilde{d}^{j} z^{k} \prod f_{u, v}^{e_{u, v}}$ with $k<n, e_{u, v}<p$, and $j+\sum p^{u} e_{u, v} \geqslant i$ form a $k$-basis, and hence the elements $\widetilde{d}^{j} z^{k} \prod f_{u, v}^{e_{u, v}}$ with $k<n, e_{u, v}<p$ and $j+\sum p^{u} e_{u, v}=i$ or $j=0$ and $\sum p^{u} e_{u, v} \geqslant i$ form a $k[\widetilde{d}]$-basis of $\bigoplus_{i^{\prime} \geqslant i} \operatorname{gr}_{\mathrm{N}}^{i^{\prime}} \widehat{\triangle}_{R / A}^{(1)}$. Analyzing their filtration, those elements with $k+n \sum p^{u} e_{u}+n \sum p^{u} e_{u, v} \in[a, b]$ form a $k[\widetilde{d}]-$ basis for $\mathrm{F}^{[a, b]} \bigoplus_{i^{\prime} \geqslant i} \operatorname{gr}_{\mathrm{N}}^{i^{\prime}} \widehat{\triangle}_{R / A}^{(1)}$. So they form a $W(k)$-basis of $\mathrm{F}^{[a, b]} \mathrm{N} \geqslant i \widehat{\triangle}_{R / A}^{(1)}$ before passing to the associated graded.

Remark 3.35. We can summarize the interaction between the generators given in Proposition 3.34 and the Nygaard and F-filtrations on $\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}$ as follows. The bigraded is concentrated below a staircase of slope $n$, with $\widetilde{d}^{j} z^{k} \prod f_{u}^{e_{u}}$ of Nygaard-filtration $j+\sum p^{u} e_{u}$ and F-filtration $k+n \sum p^{u} e_{u}$. The situation is summarized in Figure 2. Note that in the F-associated graded, the copies of $k$ generated by $\widetilde{d}^{j} z^{k} \prod f_{u}^{e_{u}}$ for varying $j$ form a copy of $W(k)$ generated by $z^{k} \prod f_{u}^{e_{u}}$.

Figure 2: Note that all monomials $\prod f_{u}^{e_{u}}$ lie on the line of slope $n$ through the origin, and everything is concentrated below the staircase depicted bold in the figure. It follows that the filtration induced by $\mathrm{F} \geqslant *$ on each $\mathrm{N}^{[a, b]} \widehat{\mathbb{}}_{R / A}^{(1)}$ is bounded above, and that the filtration induced by the Nygaard filtration on each $\mathrm{F}^{[a, b]} \widehat{\triangle}_{R / A}^{(1)}$ is complete (by $d$-completeness). See Section 2.2 for more on the interaction of the F-filtration and the Nygaard filtration.

## 4 Relative-to-absolute descent

In this section, we discuss in detail the structure of descent from the multivariable Breuil-Kisin prismatic cohomology of $\mathcal{O}_{K} / \varpi^{n}$ to its absolute prismatic cohomology. Recall the augmented cosimplicial $\delta$-ring $A^{\bullet}$

$$
W(k) \rightarrow W(k) \llbracket z_{0} \rrbracket \Longleftrightarrow W(k) \llbracket z_{0}, z_{1} \rrbracket \Longleftrightarrow \cdots
$$

which is the completion of the Amitsur complex of $W(k) \rightarrow W(k)\left\langle z_{0}\right\rangle$ at the augmented cosimplicial ideal

$$
0 \rightarrow\left(z_{0}\right) \rightleftarrows\left(z_{0}, z_{1}\right) \rightleftarrows \cdots
$$

We view $\left(A^{\bullet}, \mathcal{O}_{K}\right)$ and $\left(A^{\bullet}, \mathcal{O}_{K} / \varpi^{n}\right)$ as augmented cosimplicial $\delta$-pairs by letting $z_{0}, \ldots, z_{s}$ map to $\varpi$.
Using the prismatic envelope machinery of Section 3, we can compute the prismatic package of $\mathcal{O} / \varpi^{n}$ relative to each $A^{s}$ individually. Since the multivariable Breuil-Kisin prisms are orientable, one can trivialize away the Breuil-Kisin twist by Lemma 4.7 in computing the relative syntomic complexes $\mathbf{Z}_{p}(i)\left(\left(\mathcal{O} / \varpi^{n}\right) / A^{\bullet}\right)$
of Construction 2.21, as we explain in Section 4.2. But, the transition maps in the diagram are not compatibly maps of prisms, so in the limit the Breuil-Kisin twist is non-trivial and we must account for it. We explain how Breuil-Kisin orientations transform in Section 4.1 and study the Hopf algebroid associated to the descent diagram in the remainder of Section 4.

### 4.1 Breuil-Kisin orientations

For a prism $(B, I)$, the Breuil-Kisin twist $B\{1\}$ admits a canonical description as a limit

$$
\begin{equation*}
B\{1\}=\lim _{r} I_{r} / I_{r}^{2}=\lim \left(\cdots \rightarrow I_{3} / I_{3}^{2} \xrightarrow{\frac{\mathrm{can}}{p}} I_{2} / I_{2}^{2} \xrightarrow{\frac{\mathrm{can}}{p}} I_{1} / I_{1}^{2}\right) \tag{11}
\end{equation*}
$$

where $I_{r}=I \cdot \varphi_{B}^{*}(I) \cdots\left(\varphi_{B}^{r-1}\right)^{*}(I)$. If $B$ is transversal, the transition map $I_{r} / I_{r}^{2} \rightarrow I_{r-1} / I_{r-1}^{2}$ for $r \geqslant 2$ is characterized as the unique map which, after multiplication with $p$, agrees with the canonical map $I_{r} / I_{r}^{2} \rightarrow$ $I_{r-1} / I_{r-1}^{2}$. See [8, Sec. 2.2] for details.
Proposition 4.1. If $(B, I)$ is a prism, the natural map $B\{1\} / I_{r} \rightarrow I_{r} / I_{r}^{2}$ is an isomorphism.
Proof. This is [8, Prop. 2.2.12].
Remark 4.2. In [8, Sec. 2.2], the authors construct $B\{1\}$ as a limit as in (11) under the assumption that $B$ is transversal and they prove Proposition 4.1 in that case as well. They go on to define $B\{1\}$ in general by base change from the transversal case by showing that the category of maps to a given prism from transversal ones is sifted. However, Proposition 4.1 holds for general $B$ by base change again, since $I_{r}$ and the map involved are also obtained by base change from transversal prisms. Moreover, the limit description of $B\{1\}$ also holds in the non-transversal case, once the diagram has been obtained by base change from the transversal case. That is, for any prism $B$ there are natural maps $\frac{\text { can }}{p}: I_{r} / I_{r}^{2} \rightarrow I_{r-1} / I_{r-1}^{2}$ for $r \geqslant 2$ and a natural equivalence identifying $B\{1\}$ as the limit of the tower of (11). To see this, it is enough to check it after derived modding out by $p$, where one can use the equivalences $I_{r+1} / p \simeq I^{[r+1]_{p}} / p$. Now, the result follows from $(p, I)$-completeness.

In this section, we discuss choices of orientations on $B\{1\}$, i.e., $B$-module isomorphisms $B \cong B\{1\}$. Such isomorphisms are in bijection to choices of generators $s \in B\{1\}$ as a $B$-module.
Definition 4.3 (Breuil-Kisin orientations). For a ring $R$ and an invertible $R$-module $M$, we write

$$
\operatorname{Or}_{R}(M)
$$

for the $R^{\times}$-torsor (possibly empty) of $R$-module isomorphisms $R \rightarrow M$. For a prism $(B, I)$, we refer to $\operatorname{Or}_{B}(I)$ as the set of orientations of $B$ and $\operatorname{Or}_{B}(B\{1\})$ as the set of Breuil-Kisin orientations of $B$. The prism $(B, I)$ is orientable if $\operatorname{Or}_{B}(I)$ is nonempty and is Breuil-Kisin orientable if $\operatorname{Or}_{B}(B\{1\})$ is nonempty.
Remark 4.4. We will see in Lemma 4.7 that the existence of a Breuil-Kisin orientation is equivalent to the existence of an orientation in the usual sense (i.e. of the ideal $I$ ). However, when it comes to choices of orientations, the more natural direction is to go from a Breuil-Kisin orientation to an ordinary orientation.

Recall the following construction from [8, Const. 2.2.14].
Construction 4.5 (The Frobenius on the Breuil-Kisin twist). The Breuil-Kisin twisted Frobenius for a prism $B$ arises from a natural isomorphism of $B$-modules

$$
B\{1\} \otimes_{B, \varphi} B \xrightarrow{\cong} I^{-1} \otimes_{B} B\{1\}
$$

whose reduction $\bmod \varphi_{B}^{*}\left(I_{r}\right)$ is given by the isomorphism

where the top right vertical arrow exists because $\varphi_{B}^{*}\left(I_{r}\right)$ contains $I_{r+1}$ so that $B\{1\} \otimes_{B} B / \varphi_{B}^{*}\left(I_{r}\right) \cong B\{1\} \otimes_{B}$ $B / I_{r+1} \otimes_{B / I_{r+1}} B / \varphi_{B}^{*}\left(I_{r}\right) \cong I_{r+1} / I_{r+1}^{2} \otimes_{B / I_{r+1}} B / \varphi_{B}^{*}\left(I_{r}\right)$ by Proposition 4.1 and where the bottom arrow is an isomorphism because $\varphi_{B}^{*}\left(I_{r}\right) \cong I^{-1} I_{r+1}$. Now, $\varphi_{B\{1\}}$ is the $\varphi_{B}$-semilinear map obtained by adjunction from the composition

$$
B\{1\} \rightarrow B\{1\} \otimes_{B, \varphi} B \xrightarrow{\cong} I^{-1} \otimes_{B} B\{1\} ;
$$

it satisfies

$$
\varphi_{B\{1\}}(a s)=\varphi_{B}(a) \varphi_{B\{1\}}(s)
$$

for $a \in B$ and $s \in B\{1\}$.
Lemma 4.6. For a prism B, a Breuil-Kisin orientation $s: B \rightarrow B\{1\}$ on $B$ determines a unique orientation $d_{s} \in \operatorname{Or}(I)$ with

$$
\varphi_{B\{1\}}(a s)=d_{s}^{-1} \varphi_{B}(a) s
$$

The corresponding map

$$
\operatorname{Or}_{B}(B\{1\}) \rightarrow \operatorname{Or}_{B}(I)
$$

is equivariant with respect to the homomorphism $B^{\times} \rightarrow B^{\times}$given by

$$
u \mapsto \frac{u}{\varphi_{B}(u)} .
$$

Proof. As the map

$$
B\{1\} \otimes_{B, \varphi} B \xrightarrow{\cong} I^{-1} \otimes_{B} B\{1\}, \quad s \otimes b \mapsto b \cdot \varphi_{B\{1\}}(s)
$$

is an isomorphism, $\varphi_{B\{1\}}(s)$ is a uniquely determined generator of $I^{-1} \otimes_{B} B\{1\}$, so of the form $d_{s}^{-1} \otimes s$ for a generator $d_{s}$ of $I$. We can write $d_{s}$ symbolically as $\frac{s}{\varphi_{B\{1\}}(s)}$. It is then clear that

$$
d_{s^{\prime}}=\frac{u s}{\varphi_{B\{1\}}(u s)}=\frac{u}{\varphi_{B}(u)} d_{s}
$$

if $s^{\prime}=u s$ for a unit $u$ in $R$.
The next lemma is also proven in [8, Rem. 2.5.8].
Lemma 4.7. A prism $(B, I)$ is orientable if and only if it is Breuil-Kisin orientable.
Proof. Lemma 4.6 shows that Breuil-Kisin orientability implies orientability. For the other direction, choose an orientation $d$ of $I$. Then $I_{r} / I_{r}^{2}$ is a free $B / I_{r}$-module on the generator $d \cdot \varphi(d) \cdots \varphi^{r-1}(d)$. We now observe that, for $r \geqslant 1$, there are units $u_{r}$ such that

$$
\varphi^{r}(d)=p \cdot u_{r} \quad \bmod I_{r} .
$$

For $r=1$, this follows from

$$
\varphi(d)=p \cdot \delta(d)+d^{p}
$$

since $d$ is distinguished by hypothesis. We proceed by induction and assume that

$$
\varphi^{r}(d)=p \cdot u_{r}+S_{r}
$$

with $S_{r} \in I_{r}$. Then

$$
\begin{aligned}
\varphi^{r+1}(d) & =\varphi^{r}(d)^{p}+p \varphi^{r}(\delta(d)) \\
& =\varphi^{r}(d)^{p-1}\left(p u_{r}+S_{r}\right)+p \varphi^{r}(\delta(d)) \\
& =p\left(\varphi^{r}(\delta(d))+\varphi^{r}(d)^{p-1} u_{r}\right)+\varphi^{r}(d)^{p-1} S_{r},
\end{aligned}
$$

with $\varphi^{r}(d)^{p-1} S_{r} \in I_{r+1}$ and $u_{r+1}:=\varphi^{r}(\delta(d))+\varphi^{r}(d)^{p-1} u_{r}$ a unit since $\delta(d)$ is a unit and $\varphi^{r}(d) \in(d, p)$.

It follows that if $(B, I)$ is transversal, we can identify the unique " $\frac{1}{p}$ can" map $I_{r+1} / I_{r+1}^{2} \rightarrow I_{r} / I_{r}^{2}$ through the following commutative diagram:

In particular, the tower of $I_{r} / I_{r}^{2}$ whose limit defines $B\{1\}$ is identified with the tower of $B / I_{r}$ with transition maps given by $u_{r}$ times the canonical maps. This further identifies with the canonical tower of $B / I_{r}$ (using appropriate products of units). We get an identification $B \rightarrow B\{1\}$ in the transversal case. Since the BreuilKisin twist on non-transversal prisms is obtained by base change from an arbitrary transversal prism $\widetilde{B} \rightarrow B$ by $[8$, Sec. 2.5$]$ and since an orientable prism can always be mapped to from an orientable transversal prism (e.g. the universal oriented prism), the claim follows for arbitrary prisms.

Remark 4.8. In principle, the above proof determines a canonical way to associate to an orientation a BreuilKisin orientation. This is however not inverse to the construction of Lemma 4.6, and leads to cumbersome formulas in practice. In what follows, we will instead describe situations in which we can find preferred lifts against the construction of Lemma 4.6, i.e., preferred refinements of orientations to Breuil-Kisin orientations.

Remark 4.9. Subsequently, we will never implicitly identify $B\{i\}$ with $B$. It is therefore harmless to just write $\varphi$ both for $\varphi_{B}$ and $\varphi_{B\{i\}}$, so we will do so. This makes computations with the Breuil-Kisin twisted Frobenius notationally very intuitive: for example,

$$
\varphi\left(a s^{i}\right)=\varphi(a) \varphi(s)^{i}=d_{s}^{-i} \varphi(a) s^{i}
$$

describes the Frobenius map $B\{i\} \rightarrow I^{-i} \otimes_{B} B\{i\}$.
Lemma 4.10. If $(B,(p))$ is a crystalline prism, then there is a Breuil-Kisin orientation $s: B \rightarrow B\{1\}$ with $d_{s}=p$ which is uniquely characterized by the requirement that $s=p^{r}\left(\bmod I_{r}^{2}\right)$ in $B\{1\} / I_{r}^{2} \cong I_{r} / I_{r}^{2}$.

Proof. While there is no unique map $I_{r+1} / I_{r+1}^{2} \rightarrow I_{r} / I_{r}^{2}$ whose multiple by $p$ is the canonical map in the crystalline case, it is still true that the canonical identifications

exhibit $B\{1\}$ as the limit of some such maps; see Remark 4.2.
In the crystalline case, the limits of any two systems of such maps are canonically identified, since they differ by maps which factor through the $p$-torsion subgroups of $\left(I_{r} / I_{r}^{2}\right)$, which form a pro-nil system. The maps taking $p^{r+1}$ in $I_{r+1} / I_{r+1}^{2} \cong\left(p^{r+1}\right) /\left(p^{2 r+2}\right)$ to $p^{r}$ in $I_{r} / I_{r}^{2} \cong\left(p^{r}\right) /\left(p^{2 r}\right)$ yield one choice of such maps. We can thus canonically identify $B\{1\}$ with the limit along those maps. The collection of classes $\left[p^{r}\right]$ determine a generator $s \in B\{1\}$ in the limit.

Chasing through the diagram of isomorphisms which defines the Frobenius

$$
B\{1\} \otimes_{B, \varphi} B \cong I^{-1} \otimes_{B} B\{1\}
$$

we see that for this Breuil-Kisin orientation, $d_{s}=p$.
Definition 4.11 (Crystalline Breuil-Kisin orientation). We will refer to the Breuil-Kisin orientation constructed in Lemma 4.10 as the crystalline Breuil-Kisin orientation. Note that it is not uniquely characterized by the requirement that $d_{s}=p$ : if $B=\mathbf{Z}_{p}$, then changing $s$ by a unit $u \in \mathbf{Z}_{p}^{\times}$changes $d_{s}$ by $\frac{u}{\varphi(u)}=1$.

Remark 4.12. Bhatt and Lurie show in [8, Prop. 2.6.1] that there is a Breuil-Kisin orientation $s \in B\{1\}$ where $(B, I)$ is the $q$-de Rham prism with $B=\mathbf{Z}_{p} \llbracket q-1 \rrbracket, \varphi(q)=q^{p}$, and $I=[p]_{q}=1+q+\cdots+q^{p-1}$. Moreover, the associated orientation $d_{s}$ in this case is equal to $[p]_{q}$ by [8, Rem. 2.6.2]. Specializing along $q \mapsto 1$, one obtains a Breuil-Kisin orientation of any crystalline prism with associated orientation equal to $p$; this gives an alternative proof of Lemma 4.10.

In [4], we introduced the notion of filtered prisms $\left(\mathrm{F}^{\star} B, I\right)$. Say that a filtered prism $\left(\mathrm{F}^{\star} B, I\right)$ is crystalline if $\left(\operatorname{gr}^{0} B, I \otimes_{B} \operatorname{gr}^{0} B\right)$ is crystalline. Crystalline filtered prisms inherit canonical filtered-crystalline Breuil-Kisin orientations under the additional assumption of completeness.

Lemma 4.13. If $\left(\mathrm{F}^{\geqslant \star} A, I\right)$ is a complete filtered crystalline prism, then $(A, I)$ is orientable.
Proof. The map $I \rightarrow \operatorname{gr}_{\mathrm{F}}^{0} I$ is surjective, so choose an element $d \in I$ that reduces modulo $\mathrm{F} \geqslant 1$ to $p \in \operatorname{gr}_{\mathrm{F}}^{0} I=$ $(p) \subseteq \operatorname{gr}_{\mathrm{F}}^{0} A$. Since $\delta(d)$ is a unit modulo $\mathrm{F} \geqslant 1$ and since $\mathrm{F}^{\star} A$ is a complete filtered commutative ring, $\delta(d)$ is a unit in $A$. Thus, $(A,(d))$ is a prism and $(A,(d)) \rightarrow(A, I)$ is a map of prisms. By rigidity of prisms [11, Prop. 3.5], $I=(d)$.

Lemma 4.14. Assume $(B, I)$ is a filtered prism. If $B$ is filtered-crystalline and complete, then for any $d \in I$ whose image in $\operatorname{gr}^{0} I$ is $p$, there exists a unique lift $s: B \rightarrow B\{1\}$ of the crystalline Breuil-Kisin orientation on $\operatorname{gr}^{0} B$ with $d_{s}=d$.

Proof. Any two lifts of the crystalline Breuil-Kisin orientation differ by elements of $(1+\mathrm{F} \geqslant 1 B)^{\times} \subseteq B^{\times}$. Similarly, $d_{s}$ for such a lift differs from $d$ by an element of $(1+\mathrm{F} \geqslant 1 B)^{\times}$. The claim now follows from the observation that the map

$$
u \mapsto \frac{u}{\varphi(u)}
$$

is an automorphism of $(1+\mathrm{F} \geqslant 1 B)^{\times}$, since it agrees with the identity on the associated graded pieces as the Frobenius raises filtration weight from $m$ to $p m$.

This enables us to talk about canonical choices of Breuil-Kisin orientations on filtered crystalline prisms such as $\left(z^{\star} W(k) \llbracket z \rrbracket, E(z)\right)$, where $E(z)$ is a choice of a (not necessarily monic) Eisenstein polynomial with $E(0)=p$.

For future reference, we also record how these transform.
Lemma 4.15. Let $\left(\mathrm{F}^{\star} B, I\right)$ be a complete filtered-crystalline prism, and $d, d^{\prime}$ two generators of $I$ whose image in $\operatorname{gr}^{0} I$ is $p$. Let $u \in\left(1+\mathrm{F}^{\geqslant 1} B\right)^{\times}$with $d^{\prime}=u d$. If $s$ and $s^{\prime}$ are the canonical filtered-crystalline Breuil-Kisin orientations with $d_{s}=d$ and $d_{s^{\prime}}=d^{\prime}$, then

$$
s^{\prime}=\left(\prod_{r \geqslant 0} \varphi^{r}(u)\right) \cdot s
$$

Proof. We have $s^{\prime}=v \cdot s$ with $v \in(1+\mathrm{F} \geqslant 1 B)^{\times}$by construction. Now

$$
d_{s^{\prime}}=\frac{v}{\varphi(v)} d_{s}
$$

i.e., $\frac{v}{\varphi(v)}=u$. The unique solution $v$ is given by the product

$$
v=\prod_{r \geqslant 0} \varphi^{r}(u),
$$

which converges because the filtration $\mathrm{F}^{\star} B$ is complete and because Frobenius raises filtration weight $m$ to pm.

### 4.2 Orienting the syntomic complex

Suppose that $(A, I)$ is a prism with a Breuil-Kisin orientation $s \in A\{1\}$. Our goal in this section is to use $s$ to rewrite the relative syntomic complex of a commutative $A$-algebra $R$

$$
\mathbf{Z}_{p}(i)(R / A) \simeq \operatorname{fib}\left(\mathrm{N}^{\geqslant i} \widehat{\Delta}_{R / A}^{(1)}\{i\} \xrightarrow{\operatorname{can}-\varphi} \widehat{\mathbb{}}_{R / A}^{(1)}\{i\}\right)
$$

as an isomorphic complex

$$
\mathrm{fib}\left(\mathrm{~N}^{\geqslant i} \widehat{\mathbb{}}_{R / A}^{(1)} \xrightarrow{\text { can- } \varphi_{i}} \widehat{\mathbb{}}_{R / A}^{(1)}\right)
$$

for an appropriate divided Frobenius morphism $\varphi_{i}$.
We briefly review the Nygaard filtration and the construction of the relative syntomic complexes.
Construction 4.16. We write $\varphi_{A}^{*}$ for the $(p, I)$-completed extension of scalars along the Frobenius of $A$. Suppose that $(A, I)$ is a prism and recall the $A$-linear isomorphism $\varphi_{A}^{*}(A\{i\}) \cong I^{-i} A\{i\}$ given in Construction 4.5. Given a commutative $\bar{A}$-algebra $R$, there is an induced $A$-linear map
$\varphi_{A}^{*}\left(\triangle_{R / A}\{i\}\right) \cong \varphi_{A}^{*}\left(\triangle_{R / A}\right) \otimes_{A} \varphi_{A}^{*}(A\{i\}) \cong \varphi_{A}^{*}\left(\triangle_{R / A}\right) \otimes_{A} I^{-i} A\{i\} \xrightarrow{\varphi_{R / A} \otimes \mathrm{id}} \triangle_{R / A} \otimes_{A} I^{-i} A\{i\} \cong I^{-i} \triangle_{R / A}\{i\}$, where $\varphi_{A}^{*}\left(\triangle_{R / A}\right) \rightarrow \triangle_{R / A}$ is the relative Frobenius $\varphi_{R / A}$.
Notation 4.17. We write $\triangle_{R / A}^{(1)}\{i\}$ for $\varphi_{A}^{*}\left(\triangle_{R / A}\{i\}\right)$, despite the possibility for confusion.
Remark 4.18 (The Nygaard filtration). The Frobenius $\varphi: \triangle_{R / A}^{(1)}\{i\} \rightarrow I^{-i} \triangle_{R / A}\{i\}$ refines to a filtered map $\mathrm{N} \geqslant \star \triangle_{R / A}^{(1)} \rightarrow I^{\star-i} \triangle_{R / A}\{i\}$. In fact, this can be taken to be the defining property of $\mathrm{N}^{\geqslant \star} \triangle_{R / A}\{i\}$ in the case when $\mathrm{L}_{R / A}$ has $p$-complete Tor-amplitude in $[1,1]$. In that case, $\mathrm{N} \geqslant j \triangle_{R / A}^{(1)}\{i\}$ is defined to be the non-derived pullback

for $j \geqslant 0$. For details, see [11, Thm. 15.2].
Definition 4.19 (The Breuil-Kisin orientation on the Frobenius twist). Suppose that $A$ is a prism with a Breuil-Kisin orientation $s$. In this case, there is an induced $A$-linear isomorphism $\triangle_{R / A}^{(1)} \xrightarrow{w\left(s^{i}\right)} \triangle_{R / A}^{(1)}\{i\}$.
Lemma 4.20. Suppose that $A$ is a prism with a Breuil-Kisin orientation $s$ and that $R$ is a commutative A-algebra. Then, there is a natural commutative diagram

for some $A$-linear map $\varphi_{i, R / A}$. If $x \in \mathrm{~N}^{\geqslant i} \triangle_{R / A}^{(1)}$, then $\varphi_{i, R / A}(x)=\frac{\varphi_{R / A}}{d_{s}^{i}}$, where $d_{s}$ is the orientation associated to the Breuil-Kisin orientation s.
Proof. Existence follows from the fact that $w\left(s^{i}\right)$ and $s^{i}$ are isomorphisms. Given $x \in \widehat{\mathbb{}}_{R / A}^{(1)}$, we have that

$$
\varphi_{R / A}\left(x w\left(s^{i}\right)\right)=d_{s}^{-i} \varphi_{R / A}(x) s^{i}=\varphi_{i, R / A}(x) s^{i}
$$

where the first equality is by construction and the second is by commutativity of the diagram and the definition of $\varphi_{i, R / A}$. As $s^{i}$ is invertible it follows that $\varphi_{i, R / A}(x)=d_{s}^{-i} \varphi_{R / A}(x)$ in $I^{-i} \Delta_{R / A}$. Now, if $x \in$ $\mathrm{N} \geqslant i \Delta_{R / A}^{(1)}$, then we can write $\varphi_{i, R / A}(x)=d_{s}^{-i} \varphi_{i, R / A}(x)$ in $\triangle_{R / A}$, as desired.

Definition 4.21. Let $s$ be a Breuil-Kisin orientation of a prism $A$ and let $R$ be a commutative ring. We define

$$
\varphi_{i, R / A}(x)=\frac{\varphi_{R / A}(x)}{d_{s}^{i}}
$$

for $x \in \mathrm{~N}^{\geqslant i} \Delta_{R / A}^{(1)}$. This is the $i$ th relative divided Frobenius.
Definition 4.22. The square

is naturally commutative. It follows that by composing $\varphi_{i, R / A}$ with $w: \Delta_{R / A} \rightarrow \Delta_{R / A}^{(1)}$, one obtains a map

$$
\varphi_{i}: \mathrm{N}^{\geqslant i} \triangle_{R / A}^{(1)} \rightarrow \triangle_{R / A}^{(1)},
$$

semilinear with respect to the Frobenius on $\mathbb{\triangle}_{R / A}^{(1)}$ and which satisfies

$$
\varphi_{i}(x)=\frac{\varphi(x)}{\varphi(d)^{i}}
$$

This follows from the fact that $w$ is $\varphi$-semilinear, so $w(d)=\varphi(d)$, and $w \circ \varphi_{R / A}=\varphi_{\Delta_{R / A}^{(1)}}$.
Definition 4.23 (Oriented syntomic complexes). Both can, $\varphi_{i}: \mathrm{N}^{\geqslant i} \triangle_{R / A}^{(1)} \rightarrow \triangle_{R / A}^{(1)}$ descend to the Nygaardcompletions to give maps can, $\varphi_{i}: \mathrm{N}^{\geqslant} \widehat{\Delta}_{R / A}^{(1)} \rightarrow \widehat{\mathbb{}}_{R / A}^{(1)}$. Fix a prism $A$ and a commutative $\bar{A}$-algebra $R$. If $s$ is a Breuil-Kisin orientation of $A$, then the oriented syntomic complex $\mathbf{Z}_{p}(i)\left(R / A, s^{i}\right)$ is defined as

$$
\operatorname{fib}\left(\mathrm{N} \geqslant i \widehat{\triangle}_{R / A}^{(1)} \xrightarrow{\operatorname{can}-\varphi_{i}} \widehat{\triangle}_{R / A}^{(1)}\right)
$$

Proposition 4.24. If $A$ is a prism, $R$ is a commutative $\bar{A}$-algebra, and $s$ is a Breuil-Kisin orientation for $A$, then there is an equivalence

$$
\mathbf{Z}_{p}(i)\left(R / A, s^{i}\right) \simeq \mathbf{Z}_{p}(i)(R / A)
$$

natural in $R$ and the pair $(A, s)$.
Proof. The proposition follows from Lemma 4.20, the commutativity of (12), and the compatibility of the Nygaard filtrations on $\triangle_{R / A}^{(1)}$ and $\triangle_{R / A}^{(1)}\{i\}$ with the Breuil-Kisin twists under the orientations $s^{i}$.

### 4.3 The descent diagram

Let $\mathcal{O}_{K}$ be a DVR with perfect residue field $k$, uniformizer $\varpi$, and Eisenstein polynomial $E\left(z_{0}\right) \in W(k) \llbracket z_{0} \rrbracket$. There is a prism structure on $W(k) \llbracket z_{0} \rrbracket$ with $d=E\left(z_{0}\right)$. Let $R=\mathcal{O}_{K} / \varpi^{n}$. Then

$$
\triangle_{R / W(k) \llbracket z_{0} \rrbracket}=W(k) \llbracket z_{0} \rrbracket\left\{\frac{z_{0}^{n}}{E\left(z_{0}\right)}\right\} .
$$

More generally, we have a prism structure on $W(k) \llbracket z_{0}, \ldots, z_{s} \rrbracket$, given (somewhat arbitrarily) by the ideal $\left(E\left(z_{0}\right)\right)$. We have

$$
\triangle_{R / W(k) \llbracket z_{0}, \ldots, z_{s} \rrbracket}=W(k) \llbracket z_{0}, \ldots, z_{s} \rrbracket\left\{\frac{z_{0}^{n}}{E\left(z_{0}\right)}, \frac{z_{1}-z_{0}}{E\left(z_{0}\right)}, \ldots, \frac{z_{s}-z_{0}}{E\left(z_{0}\right)}\right\}^{\wedge}
$$

where we take all $z_{j} \mapsto \varpi$. These are more natural than we expect from the description. For example, there should be a map from $\triangle_{R / W(k) \llbracket z_{0} \rrbracket} \rightarrow \triangle_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}$ taking $z_{0} \mapsto z_{1}$, even though that does not define a map
on the base prisms. The problem is the arbitrary choice of ideal $\left(E\left(z_{0}\right)\right)$ : The map $z_{0} \mapsto z_{1}$ is only compatible with the prism structure defined by $\left(E\left(z_{1}\right)\right)$ instead. These different choices do however become equivalent in $\mathbb{\triangle}_{R / W(k) \llbracket z_{0}, \ldots, z_{s} \rrbracket}$, as one can see from the prismatic envelope description: $E\left(z_{j}\right)-E\left(z_{0}\right)$ is divisible by $z_{j}-z_{0}$, and is thus being made divisible by $E\left(z_{0}\right)$, since the prismatic envelope contains an element $\frac{z_{j}-z_{0}}{E\left(z_{0}\right)}$. In fact, the various $E\left(z_{j}\right)$ become unit multiples of each other in the prismatic envelope. Hence the above prismatic envelope also contains elements $\frac{z_{j^{\prime}}-z_{0}}{E\left(z_{j}\right)}$ for $0 \leqslant j, j^{\prime} \leqslant s$ and satisfies the universal property of the prismatic envelope describing prismatic cohomology relative to the prism structure $\left(E\left(z_{j}\right)\right)$ on the base.

In [4], this idea is used to systematically extend prismatic cohomology to a functor defined on the category of $\delta$-pairs $(A, R)$, where $A$ is a $\delta$-ring and $R$ an $A$-algebra in such a way that, for a prism $(A, I)$ and an $A / I$-algebra $R$, it agrees with derived prismatic cohomology in the sense of [11], and, for $A=\mathbf{Z}$, it agrees with absolute prismatic cohomology in the sense of [8]. This additional functoriality allows us to make the following statement.

Lemma 4.25. For a perfect $\mathbf{F}_{p}$-algebra $k$ and a $W(k) \llbracket z_{0} \rrbracket$-algebra $R$, we have

$$
\Delta_{R}\{i\} \simeq \mathbb{\Delta}_{R / W(k)}\{i\} \simeq \operatorname{Tot}\left(\triangle_{R / W(k) \llbracket z_{0} \rrbracket}\{i\} \Longleftrightarrow \Delta_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}\{i\} \Longleftrightarrow \ldots\right)
$$

and

$$
\widehat{\mathbb{}}_{R / W(k)}^{(1)}\{i\} \simeq \operatorname{Tot}\left(\widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightleftarrows \widehat{\triangle}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}\{i\} \Longleftrightarrow \ldots\right)
$$

for all weights $i \in \mathbf{Z}$.
Proof. See [4, Thm. 1.2(6)].
We will call the cosimplicial diagrams of Lemma 4.25 the relative-to-absolute descent diagrams for absolute prismatic cohomology and Nygaard-complete absolute prismatic cohomology, respectively. They give prismatic cohomology analogues of the approach to TP and TC pioneered by Liu and Wang in [33]. Note that in the case $R=\mathcal{O}_{K} / \varpi^{n}$, all terms appearing in the diagrams are discrete, and thus the totalization is represented by the total complex of the diagram. In this case, we will also call this diagram the relative-toabsolute descent complex. There is also an F-completed version of the untwisted relative-to-absolute descent diagram which will play a role in the arguments below.

Notation 4.26. If $\left(\mathrm{F}^{\star} A, \mathrm{~F}^{\star} R\right)$ is a filtered $\delta$-pair in the sense of [4], then $\triangle_{R / A}$ admits an associated F filtration $\mathrm{F}^{\star} \Delta_{R / A}$. We will write $\widehat{\triangle}_{R / A}$ for the completion of $\Delta_{R / A}$ with respect to $\mathrm{F}^{\star}$. If $A=\mathbf{Z}_{p}$ with the trivial filtration, we write $\widehat{\mathbb{}}_{R}$ for $\widehat{\mathbb{}}_{R / \mathbf{z}_{p}}$.
Warning 4.27. Recall that for rings $R$ such as $\mathcal{O}_{K}$ or $\mathcal{O}_{K} / \varpi^{n}$, the Nygaard completion $\widehat{\triangle}_{R / W(k) \llbracket z_{0}, \ldots, z_{s} \rrbracket}^{(1)}$ agrees with the F-completion of $\triangle_{R / W(k) \llbracket z_{0}, \ldots, z_{s} \rrbracket}^{(1)}$ by Theorem 2.20. In [10, 8], the Nygaard filtration is constructed on absolute prismatic cohomology $\triangle_{R}$ and one typically writes $\widehat{\Delta}_{R}$ for the completion with respect to the Nygaard filtration. In general, this conflicts with our notation. However, for rings $R$ such as $\mathcal{O}_{K}$ or $\mathcal{O}_{K} / \varpi^{n}$, the two completions agree using an argument similar to that of Theorem 2.20. In this paper, $\widehat{\triangle}_{R / A}$ will always denote the completion of $\Delta_{R / A}$ with respect to the F -filtration induced by a filtration on the $\delta$-pair $(A, R)$ while $\widehat{\triangle}_{R / A}^{(1)}$ will always denote the completion of $\Delta_{R / A}^{(1)}$ with respect to the Nygaard filtration.

Definition 4.28. By Lemma 4.25 for a filtered commutative $z_{0}^{\star} W(k) \llbracket z_{0} \rrbracket$-algebra $R$, there is an induced equivalence

$$
\widehat{\triangle}_{R}\{i\} \simeq \widehat{\triangle}_{R / W(k)}\{i\} \simeq \operatorname{Tot}\left(\widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}\{i\} \Longleftrightarrow \widehat{\triangle}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}\{i\} \Longleftrightarrow \ldots\right)
$$

We will refer to this as the F-completed relative-to-absolute descent diagram for absolute prismatic cohomology.

The relative-to-absolute descent diagrams are the cobar complexes associated to Hopf algebroids, as we now explain.

Definition 4.29 (Hopf algebroids). A Hopf algebroid consists of a pair of commutative rings $\left(\Gamma_{0}, \Gamma_{1}\right)$ with maps
(1) $\eta_{L}, \eta_{R}: \Gamma_{0} \rightarrow \Gamma_{1}$,
(2) $\varepsilon: \Gamma_{1} \rightarrow \Gamma_{0}$,
(3) $\iota: \Gamma_{1} \rightarrow \Gamma_{1}$, and
(4) $\Delta: \Gamma_{1} \rightarrow \Gamma_{1} \otimes_{\eta_{R}, \Gamma_{0}, \eta_{L}} \Gamma_{1}$
fulfilling various identities which make the pair $\left(\operatorname{Spec} \Gamma_{0}, \operatorname{Spec} \Gamma_{1}\right)$ into a groupoid object in the category of affine schemes. See [38, App. 1] for details.
Definition 4.30 (Comodules). For a Hopf algebroid $\left(\Gamma_{0}, \Gamma_{1}\right)$, a (right) comodule is given by a right $\Gamma_{0^{-}}$ module $M$ together with a coaction map $M \rightarrow M \otimes_{\Gamma_{0}} \Gamma_{1}$, which is a right $\Gamma_{0}$-module map and which satisfies counit and coassociative identities as in [38, App. 1].
Definition 4.31. The cobar complex of a Hopf algebroid $\left(\Gamma_{0}, \Gamma_{1}\right)$ is a cosimplicial commutative ring $\operatorname{coBar}\left(\Gamma_{0}, \Gamma_{1}\right)$ of the form

$$
\Gamma_{0} \rightleftarrows \Gamma_{1} \rightleftarrows \Gamma_{1} \otimes_{\Gamma_{0}} \Gamma_{1} \cdots
$$

To a comodule $M$ over $\left(\Gamma_{0}, \Gamma_{1}\right)$, there is an associated cobar complex coBar $(M)$, taking the form

$$
M \rightleftarrows M \otimes_{\Gamma_{0}} \Gamma_{1} \rightleftarrows M \otimes_{\Gamma_{0}} \Gamma_{1} \otimes_{\Gamma_{0}} \Gamma_{1} \cdots
$$

which is a cosimplicial module over $\operatorname{coBar}\left(\Gamma_{0}, \Gamma_{1}\right)$. See [38, Def. A1.2.11] for a reference to the reduced version of this construction.

Remark 4.32. Analogous definitions make sense in (complete) filtered commutative rings and modules.
Construction 4.33. Consider the Hopf algebroid $\left(W(k) \llbracket z_{0} \rrbracket, W(k) \llbracket z_{0}, z_{1} \rrbracket\right)$ in commutative $W(k)$-algebras, where
(1) $\eta_{L}\left(z_{0}\right)=z_{0}$ and $\eta_{R}\left(z_{0}\right)=z_{1}$,
(2) $\epsilon\left(z_{0}\right)=\epsilon\left(z_{1}\right)=z_{0}$,
(3) $\iota\left(z_{0}\right)=z_{1}$ and $\iota\left(z_{1}\right)=z_{0}$, and
(4) $\Delta\left(z_{0}\right)=z_{0}$ and $\Delta\left(z_{1}\right)=z_{2}$ under the identification

$$
W(k) \llbracket z_{0}, z_{1} \rrbracket \otimes_{\eta_{R}, W(k) \llbracket z_{0} \rrbracket, \eta_{L}} W(k) \llbracket z_{0}, z_{1} \rrbracket \cong W(k) \llbracket z_{0}, z_{1}, z_{2} \rrbracket .
$$

Write $W(k) \llbracket z_{\bullet} \rrbracket$ for the cobar complex of this Hopf algebroid, which agrees with the (completed) descent complex of $W(k) \rightarrow W(k) \llbracket z_{0} \rrbracket$. If $R$ is a commutative $W(k) \llbracket z_{0} \rrbracket$-algebra, we can consider the pair of pairs

$$
\left(\left(R / W(k) \llbracket z_{0} \rrbracket\right),\left(R / W(k) \llbracket z_{0}, z_{1} \rrbracket\right)\right)
$$

which is a Hopf algebroid in the category of $\delta$-pairs.
Lemma 4.34. Suppose that $R$ is a commutative $W(k) \llbracket z_{0} \rrbracket$-algebra such that $\mathrm{L}_{R / W(k) \llbracket z_{0} \rrbracket}$ has p-complete Tor-amplitude in $[0,1]$.
(a) The pair $\left(\mathbb{Q}_{R / W(k) \llbracket z_{0} \rrbracket}, \triangle_{\left.R / W(k) \llbracket z_{0}, z_{1} \rrbracket\right)}\right)$ forms a complete filtered Hopf algebroid (with respect to the Hodge-Tate filtration) and the local-to-global descent complex $\triangle_{R / W(k) \llbracket \varepsilon_{\bullet} \rrbracket}$ identifies with its cobar complex.
(b) For each integer $i$, the ith Breuil-Kisin twist $\triangle_{R / W(k) \llbracket z_{0} \rrbracket}\{i\}$ is a comodule over the Hopf algebroid of part (a) and the descent complex $\triangle_{R / W(k) \llbracket z_{\bullet} \rrbracket}\{i\}$ identifies with its cobar complex.

Proof. We can apply prismatic cohomology (in the sense of [4]) pointwise to the cobar complex of the Hopf algebroid in $\delta$-rings of Construction 4.33. This produces the local-to-global descent complex computing absolute prismatic cohomology of Lemma 4.25. For each $i \in \mathbf{Z}, s \geqslant 2$, and $0 \leqslant j \leqslant s$, the natural map
is an equivalence by symmetric monoidality of prismatic cohomology for prismatic $\delta$-pairs, which follows for example from the compatibility of relative (derived) Cartier-Witt stacks with limits of schemes and the affineness of all such stacks in question (see [9, Thm. 7.17]), and by functoriality of the Breuil-Kisin twists [8, Prop. 2.5.1]. Taking $s=2$ and $j=1$ produces the comultiplication $\Delta$. For $s>2$, one learns that the cobar complex is indeed isomorphic to the local-to-global descent complex. This completes the proof.
Remark 4.35. The F-completion $\left(\mathrm{F}^{\star} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}, \mathrm{~F}^{\star} \widehat{\triangle}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}\right)$ of the Hopf algebroid of Lemma 4.34 is a Hopf algebroid in complete $p$-complete filtered complexes (with respect to the F-filtration) and the Fcompleted relative-to-absolute descent diagram is its cobar complex. A result analogous to Lemma 4.34(2) holds for the Breuil-Kisin twists.

The analogous statements hold with Frobenius twists, and the proof is similar. For the relevant symmetric monoidality of the Nygaard-completed Frobenius twists, one can reduce to the associated graded pieces of the Nygaard filtration and hence to the conjugate filtered pieces of Hodge-Tate cohomology where it follows using symmetric monoidality of $p$-completed derived differential forms $\widehat{\mathrm{L} \Omega}_{-/-}^{*}$.

Lemma 4.36. (a) The pair $\left(\widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}, \widehat{\triangle}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}\right)$ forms a complete filtered Hopf algebroid (with respect to the Nygaard filtration), and the descent complex $\widehat{\triangle}_{R / W(k) \llbracket z_{\bullet} \rrbracket}^{(1)}$ identifies with its cobar complex.
(b) For each integer $i$, the ith Breuil-Kisin twist $\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\}$ is a comodule over the Hopf algebroid of part (a) and the local-to-global descent complex $\widehat{\triangle}_{R / W(k) \llbracket z_{\bullet} \rrbracket}^{(1)}\{i\}$ identifies with its cobar complex.

### 4.4 Structure maps of the descent complex

We now describe the structure maps in detail for $R=\mathcal{O}_{K} / \varpi^{n}$. From now on, we will be using F-completed prismatic cohomology $\widehat{\triangle}_{R / A}$. In this case,

$$
\widehat{\Delta}_{R / W(k) \llbracket z_{0} \rrbracket}=W(k) \llbracket z_{0} \rrbracket\left\{\frac{z_{0}^{n}}{E\left(z_{0}\right)}\right\}_{p, E\left(z_{0}\right)}^{\wedge}
$$

is an F-completely free $W(k)$-module on monomials $z_{0}^{k} \prod_{u} \delta^{u}(a)^{e_{u}}$ for $k<n$ and $e_{u}<p$, where $a=\frac{z_{0}^{n}}{E\left(z_{0}\right)}$ by Proposition 3.33. On

$$
\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}=W(k) \llbracket z_{0} \rrbracket\left\{\frac{z_{0}^{n}}{E\left(z_{0}\right)}, \frac{z_{1}-z_{0}}{E\left(z_{0}\right)}\right\}_{p}^{\wedge}
$$

we similarly have a $W(k)$-basis of monomials $z_{0}^{k} \prod_{u} \delta^{u}(a)^{e_{u}} \prod_{u} \delta^{u}(b)^{e_{u}^{\prime}}$ with $k<n$ and $e_{u}, e_{u}^{\prime}<p$, where $a=\frac{z_{0}^{k}}{E\left(z_{0}\right)}$ and $b=\frac{z_{1}-z_{0}}{E\left(z_{0}\right)}$.

Observe that the two orientations $E\left(z_{1}\right)$ and $E\left(z_{0}\right)$ of $\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}$ differ by the factor

$$
u=\frac{E\left(z_{1}\right)}{E\left(z_{0}\right)}=1+\frac{E\left(z_{1}\right)-E\left(z_{0}\right)}{z_{1}-z_{0}} b
$$

By Lemma 4.15, the corresponding filtered-crystalline Breuil-Kisin orientations $s_{0}$ and $s_{1}$ compatible with

Lemma 4.37. The structure maps in the Hopf algebroid $\left(\widehat{\triangle}_{R / W(k)} \llbracket z_{0} \rrbracket, \widehat{\triangle}_{R / W(k)} \llbracket z_{0}, z_{1} \rrbracket\right)$ are determined, in terms of the prismatic envelope description of Proposition 3.33, by noting that
(i) $\eta_{L}: \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket} \rightarrow \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}$ takes $z_{0} \mapsto z_{0}$ and $a \mapsto a$;
(ii) $\eta_{R}: \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket} \rightarrow \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}$ takes

$$
z_{0} \mapsto z_{1}=z_{0}+E\left(z_{0}\right) \cdot b
$$

and

$$
a \mapsto \frac{z_{1}^{n}}{E\left(z_{1}\right)}=\frac{\left(z_{0}+E\left(z_{0}\right) b\right)^{n}}{E\left(z_{0}\right)} \cdot u^{-1}
$$

(iii) $\varepsilon: \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket} \rightarrow \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}$ takes $z_{0} \mapsto z_{0}, a \mapsto a$, and $b \mapsto 0 ;$
(iv) $\iota: \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket} \rightarrow \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}$ takes $z_{0} \mapsto \eta_{R}\left(z_{0}\right)=z_{1}$, $a \mapsto \eta_{R}(a)$, and

$$
b \mapsto \frac{z_{0}-z_{1}}{E\left(z_{1}\right)}=-b u^{-1}
$$

(v) $\Delta: \widehat{\triangle}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket} \rightarrow \widehat{\triangle}_{R / W(k) \llbracket z_{0}, z_{1}, z_{2} \rrbracket} \cong \widehat{\triangle}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket} \otimes_{\eta_{R}, \Delta_{R / W(k) \llbracket z_{0} \rrbracket}, \eta_{L}} \widehat{\triangle}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}$ takes $z_{0} \mapsto$ $z_{0} \otimes 1, a \mapsto a \otimes 1$, and

$$
b=\frac{z_{1}-z_{0}}{E\left(z_{0}\right)} \mapsto \frac{z_{2}-z_{0}}{E\left(z_{0}\right)}=\frac{z_{1}-z_{0}}{E\left(z_{0}\right)}+\frac{z_{2}-z_{1}}{E\left(z_{1}\right)}\left(1+\frac{E\left(z_{1}\right)-E\left(z_{0}\right)}{z_{1}-z_{0}} b\right)=b \otimes 1+u \otimes b
$$

The values on the remaining generators are determined by compatibility of the structure maps with the $\delta$-ring structures.

Proof. This follows from the description as prismatic envelope.
For the Frobenius-twisted term, we have a similar description. Recall from Proposition 3.34 that

$$
\widehat{凶}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}=W(k) \llbracket z_{0} \rrbracket\left\{\frac{z_{0}^{p n}}{\varphi\left(E\left(z_{0}\right)\right)}\right\}^{\wedge}
$$

is F-completely $W(k)$-free on monomials $z_{0}^{k} \prod f_{u}^{e_{u}}$ where $k<n$ and $e_{u}<p$, and

$$
\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}=W(k) \llbracket z_{0}, z_{1} \rrbracket\left\{\frac{z_{0}^{p n}}{\varphi\left(E\left(z_{0}\right)\right)}, \frac{z_{1}^{p}-z_{0}^{p}}{\varphi\left(E\left(z_{0}\right)\right)}\right\}^{\wedge}
$$

is F-completely $W(k)$-free on monomials $z_{0}^{k} \prod f_{u}^{e_{u}} \prod g_{u}^{e_{u}^{\prime}}$ where $k<n, e_{u}<p, e_{u}^{\prime}<p$. Here $f_{0}$ is $z_{0}^{n}$, viewed as element of $\mathrm{N} \geqslant 1 \widehat{\Delta}^{(1)}, g_{0}$ is $z_{1}-z_{0}$, viewed as element of $\mathrm{N} \geqslant 1 \widehat{\Perp}^{(1)}$, and $f_{u}$ and $g_{u}$ arise from iterating $\widetilde{\delta}: N \geqslant * \widehat{\Delta}^{(1)} \rightarrow \mathrm{N} \geqslant p \star \widehat{\Delta}^{(1)}$.
Lemma 4.38. The structure maps in the Hopf algebroid $\left(\widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}, \widehat{\mathbb{\Delta}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}\right)$ are determined, in terms of the prismatic envelope description of Proposition 3.34, by noting that
(a) $\eta_{L}$ takes $z_{0} \mapsto z_{0}$ and $f_{0} \mapsto f_{0}$;
(b) $\eta_{R}$ takes $z_{0} \mapsto z_{1}=z_{0}+g_{0}$ and $f_{0} \mapsto\left(z_{0}+g_{0}\right)^{n}$;
(c) $\varepsilon$ takes $z_{0} \mapsto z_{0}, f_{0} \mapsto f_{0}$ and $g_{0} \mapsto 0$;
(d) $\iota$ takes $z_{0} \mapsto \eta_{R}\left(z_{0}\right)=z_{0}+g_{0}, f_{0} \mapsto \eta_{R}\left(f_{0}\right)=\left(z_{0}+g_{0}\right)^{n}$ and $g_{0} \mapsto z_{0}-z_{1}=-g_{0}$;
(e) $\Delta$ takes $z_{0} \mapsto z_{0}, f_{0} \mapsto f_{0}$, and $g_{0} \mapsto z_{2}-z_{0}=\left(z_{1}-z_{0}\right)+\left(z_{2}-z_{1}\right)=g_{0} \otimes 1+1 \otimes g_{0}$.

The values on the other generators are determined by compatibility of the structure maps with the $\delta$-ring structures.

Note that the maps in Lemma 4.38 are not compatible with the operations $\widetilde{\delta}$, since they depend on the orientation, so one has to use the formulas for $\delta$ on the $f_{u}$ and $g_{u}$ generators from Section 3.4. Alternatively, one can consider different versions of $\widetilde{\delta}$ and how to translate them into each other. In the algorithm we have implemented, we use an alternative approach to compute the map $\nabla$ from Definition 4.41; see Section 4.5. For the proof of Lemma 4.38, it will suffice to determine the structure maps on the associated graded of the F-filtration, which we do below in Lemma 4.51.

Finally, we describe the comodule structure on $\widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}\{i\}$ and $\widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\}$. Recall from Lemma 4.14
 crystalline Breuil-Kisin orientation with $\varphi(s)=\frac{s}{E\left(z_{0}\right)}$. Note that this implies that $\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\}$ is a free $\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}$-module on $w\left(s^{i}\right)$.

Lemma 4.39. The coaction

$$
\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}\{i\} \rightarrow \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}\{i\} \simeq \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}\{i\} \otimes_{\widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}
$$

takes $s^{i} \mapsto v^{i} s^{i}$ where

$$
v=\prod_{r \geqslant 0} \varphi^{r}(u)
$$

Proof. The map is induced by $z_{0} \mapsto z_{1}$. So it takes the filtered-crystalline Breuil-Kisin orientation $s$ with $d_{s}=E\left(z_{0}\right)$ to the filtered-crystalline Breuil-Kisin orientation $s_{R}$ with $d_{s_{R}}=E\left(z_{1}\right)$. Since

$$
u=\frac{E\left(z_{1}\right)}{E\left(z_{0}\right)}
$$

we have $d_{s_{R}}=u d_{s}$, and so

$$
s \mapsto v s
$$

with $v=\prod_{r \geqslant 0} \varphi^{r}(u)$ by Lemma 4.15.
Lemma 4.40. The coaction

$$
\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}\{i\} \simeq \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \otimes_{\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}
$$

takes $w\left(s^{i}\right)$ to $w\left(v^{i}\right) \cdot w\left(s^{i}\right)$.
Proof. This follows by applying $w$ to the result of Lemma 4.39.

### 4.5 The connection

In the case of $R=\mathcal{O}_{K}$ or $\mathcal{O}_{K} / \varpi^{n}$, one can show using the Hodge-Tate comparison theorem in absolute prismatic cohomology [8] that $\widehat{\Delta}_{R}$ and $\widehat{\Delta}_{R}^{(1)}$ are cohomologically 1-dimensional. This means that, in these cases, the relative-to-absolute descent complexes are quasi-isomorphic to the 2 -term complexes

$$
\begin{align*}
& \widehat{\mathbb{\Delta}}_{R / W(k) \llbracket z_{0} \rrbracket}\{i\} \rightarrow \operatorname{ker}\left(\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}\{i\} \rightarrow \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1}, z_{2} \rrbracket}\{i\}\right), \\
& \widehat{\mathbb{\Delta}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \operatorname{ker}\left(\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}\{i\} \rightarrow \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1}, z_{2} \rrbracket}^{(1)}\{i\}\right) \tag{13}
\end{align*}
$$

obtained as their good truncations $\tau^{\leqslant 1}$. In this section, we want to produce a more explicit description of the second term, reproducing the statement about the cohomological dimension along the way.

It follows from Proposition 3.33 that $\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}$ is F-completely free as a $\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}$-module, on generators $\prod \delta^{u}(b)^{e_{u}}$ with $e_{u}<p$. Similarly, $\widehat{\triangle}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}$ is F-completely free as a $\widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket^{(1)}}^{-m o d u l e, ~ o n ~}$ generators $\prod g_{u}^{e_{u}}$ with $e_{u}<p$.

Definition 4.41. We define maps

$$
\begin{gathered}
\theta: \mathrm{F}^{\geqslant \star} \widehat{\Delta}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}\{i\} \rightarrow \mathrm{F}^{\geqslant \star-1} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}\{i-1\}=: \mathrm{F} \geqslant \star \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}\{i\} \\
\theta: \mathrm{F}^{\geqslant \star} \mathrm{N}^{\geqslant \star} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}\{i\} \rightarrow \mathrm{F}^{\geqslant \star-1} \mathrm{~N}^{\geqslant \star-1} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i-1\}=: \mathrm{F} \geqslant \star \mathrm{~N}^{\geqslant \star} \widehat{\Delta}_{R / W(k), z_{0} \rrbracket}^{(1), \nabla}\{i\}
\end{gathered}
$$

 first line, and as the $\widehat{\mathbb{}}_{R / W(k)}^{(1)} \llbracket z_{0} \rrbracket$-linear map taking $g_{0} \cdot w\left(s^{i}\right) \mapsto w\left(s^{i-1}\right)$ and all other basis monomials $\prod g_{u}^{e_{u}} \cdot w\left(s^{i}\right) \mapsto 0$ for the second line. We then define maps

$$
\begin{gathered}
\nabla: \mathrm{F}^{\geqslant \star} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}\{i\} \rightarrow \mathrm{F}^{\geqslant \star} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}\{i\} \\
\nabla: \mathrm{F}^{\geqslant \star} \mathrm{N}^{\geqslant \star} \widehat{\Delta}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \mathrm{F}^{\geqslant \star} \mathrm{N}^{\geqslant \star} \widehat{\Delta}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}
\end{gathered}
$$

as the composite of the first differential $\eta_{R}-\eta_{L}$ of the descent complexes with $\theta$.
Remark 4.42. Note that we define the $\Delta^{\nabla}$ terms with shifted $F$ and Nygaard filtrations. Additionally, this where the F-completion of relative prismatic is necessary as the map $\theta$ is defined only with respect to an F-complete basis.

In Sections 4.6 and 4.7, we will prove the following lemma.
Lemma 4.43. There are commutative diagrams

and

where the top rows in each case are the cochain complexes associated to the relative-to-absolute descent diagrams, and the vertical map induces a quasi-isomorphism between the rows.

Note that the upper horizontal map is not $\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}$-linear, so the bottom horizontal map is also not a linear map. Additionally, the next differential in the upper complex is not linear, so while the above lemma implies that the restriction of $\theta$ defines an isomorphism between the kernel term in Equation 13 and $\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}$, that isomorphism is not a module map with respect to any a priori defined module structure on the kernel. In fact, the whole identification is non-canonical in the sense that if we switch the roles of $z_{0}$ and $z_{1}$, we obtain different maps $\theta$ and $\nabla$. It is an interesting problem to give $\nabla$ and its codomain a more invariant interpretation, but we will not pursue this here. A more canonical version of this type of connection exists in the $q$-de Rham setting, see [24].
Corollary 4.44. The syntomic complex $\mathbf{Z}_{p}(i)(R)$ with its F -filtration identifies with the total fiber of a square
for some map $\varphi^{\nabla}$. (Compare Definition 4.54 below.)
Proof. By definition and the fact that prismatic cohomology is 1-dimensional, the syntomic complex identifies with the total fiber of

where $K$ denotes the kernel of the second differential in the descent complex. By Lemma 4.43, the restriction of $\theta$ to $K$ is an isomorphism. By transporting the maps can and $\varphi$ along $\left.\theta\right|_{K}$, we thus obtain the claim. Note that although $\theta$ is not a module map, it commutes with can (see Lemma 4.55), so can appears unchanged in the square above.

Remark 4.45. The map $\varphi^{\nabla}$ can in fact be characterized uniquely by commutativity of the square above, since we will see that $\nabla$ is F-completely a rational isomorphism, and all involved terms are torsion-free. In the algorithmic application of Corollary 4.44, we can therefore avoid explicitly computing $K$ and $\theta$.

### 4.6 Generalities about Hopf algebroid operations

In this section, let $\Gamma=\left(\Gamma_{0}, \Gamma_{1}\right)$ be a Hopf algebroid where $\Gamma_{1}$ is free as a left $\Gamma_{0}$-module.
Definition 4.46. For a left $\Gamma_{0}$-linear map $\theta: \Gamma_{1} \rightarrow \Gamma_{0}$, we obtain a transformation

$$
\nabla_{\theta}: M \rightarrow M
$$

natural in right $\Gamma$-comodules $M$, as the composite

$$
M \rightarrow M \otimes_{\Gamma_{0}} \Gamma_{1} \xrightarrow{\mathrm{id} \otimes \theta} M
$$

Lemma 4.47. The above construction determines an equivalence between the set of left linear homomorphisms $\Gamma_{1} \rightarrow \Gamma_{0}$ and the set of natural endomorphisms

$$
M \rightarrow M
$$

of the forgetful functor from right $\Gamma$-comodules to abelian groups.
Proof. We may evaluate a natural endomorphism $\nabla$ on $\Gamma_{1}$ to obtain a map

$$
\nabla: \Gamma_{1} \rightarrow \Gamma_{1}
$$

which is a left $\Gamma_{0}$-module homomorphism by naturality, as the left $\Gamma_{0}$-action on $\Gamma_{1}$ is through right comodule morphisms. We may postcompose with $\varepsilon: \Gamma_{1} \rightarrow \Gamma_{0}$ to obtain a left linear homomorphism $\theta: \Gamma_{1} \rightarrow \Gamma_{0}$. We claim those constructions are inverse to each other. Starting with a left linear homomorphism $\theta: \Gamma_{1} \rightarrow \Gamma_{0}$, passing to $\nabla_{\theta}$ and forming the composite as above, we recover $\theta$, since the diagram

commutes. Conversely, if we start with a natural endomorphism $\nabla$ and obtain a left linear $\theta: \Gamma_{1} \rightarrow \Gamma_{0}$ as above, $\nabla=\nabla_{\theta}$, since the following diagram commutes:

Here $\nabla$ on $M \otimes_{\Gamma_{0}} \Gamma_{1}$ agrees with $\operatorname{id}_{M} \otimes \nabla$ by naturality of $\nabla$, since $(-) \otimes_{\Gamma_{0}} \Gamma_{1}$ is a colimit-preserving functor from right $\Gamma_{0}$-modules to right $\Gamma$-comodules.

Example 4.48. For $b_{i}$ a left $\Gamma_{0}$-basis of $\Gamma_{1}$ (possibly in some completed sense), $\theta^{i}: \Gamma_{1} \rightarrow \Gamma_{0}$ the dual basis homomorphisms, and $x \in \Gamma_{1}$, we have

$$
\Delta(x)=\sum_{i} \nabla_{\theta^{i}}(x) \otimes b_{i} .
$$

Similarly, for $x \in \Gamma_{0}$, we have

$$
\eta_{R}(x)=\sum_{i} \nabla_{\theta^{i}}(x) \cdot b_{i}
$$

Example 4.49. If $\Gamma_{1}$ is a free divided power algebra over $\Gamma_{0}$ on a generator $y$ which is primitive (meaning that $\Delta(y)=y \otimes 1+1 \otimes y)$, then

$$
\Delta\left(y^{[n]}\right)=\sum_{i} y^{[i]} \otimes y^{[n-i]}
$$

so $\nabla_{\theta}\left(y^{[n]}\right)=y^{[n-1]}$ when $\theta: \Gamma_{1} \rightarrow \Gamma_{0}$ is the dual basis element to $y$ with respect to the divided power basis, which is to say the map that takes $y \mapsto 1$ and $y^{[n]} \mapsto 0$ for $n \neq 1$. In particular, $\varepsilon \circ \nabla_{\theta}^{n}: \Gamma_{1} \rightarrow \Gamma_{0}$ is the dual basis element to $y^{[n]}$, hence after a suitable completion, every $\nabla$ may be expressed as a power series in the chosen $\nabla_{\theta}$. We also have

$$
\eta_{R}(x)=\sum_{n} \nabla_{\theta}^{n}(x) \cdot y^{[n]}
$$

for $x \in \Gamma_{0}$, and evaluating $\eta_{R}(x y)$ two ways shows a Leibniz rule

$$
\nabla_{\theta}(x y)=\nabla_{\theta}(x) y+x \nabla_{\theta}(y) .
$$

Since the sequence

$$
\begin{equation*}
0 \rightarrow \Gamma_{0} \xrightarrow{\eta_{L}} \Gamma_{1} \xrightarrow{\nabla_{\theta}} \Gamma_{1} \rightarrow 0 \tag{14}
\end{equation*}
$$

is a short exact sequence of left $\Gamma$-comodules (by direct inspection), applying the two-side cobar complex $\operatorname{coBar}_{\Gamma}(M,-)$ to (14) yields a fiber sequence

$$
\operatorname{coBar}_{\Gamma}\left(M, \Gamma_{0}\right) \rightarrow M \xrightarrow{\nabla_{\theta}} M .
$$

Remark 4.50. We will see below that the situation of the descent Hopf algebroid behaves as a deformation of this divided power situation: the $\nabla$ from Lemma 4.43 is indeed of the form discussed in this section, and while we do not have a divided power structure, it still generates all operations in a suitably completed sense, and identifies the limit of the cobar complex of $M$ with the fiber of $\nabla$ on $M$ (Lemma 4.43 is a special case of this). Since we work with the bases $\prod \delta^{u}(b)^{e_{u}}$ or $\prod g_{u}^{e_{u}}$ instead of a divided power basis, and the relations for $g_{u}^{p}$ for example may involve terms linear in $g_{0}$, the analogue of the Leibniz rule breaks down and instead involves higher correction terms. The precise behaviour is of course highly sensitive to the choice of basis, and we currently do not know whether there is a better choice of basis that leads to closed-form formulas.

### 4.7 Proof of Lemma 4.43

We need two preliminary lemmas. The first gives a set of generators of the F-associated graded pieces of the relevant prismatic envelopes which are related to, but not the same as, those given in Section 3.5.

Lemma 4.51. (i) In the Hopf algebroid $\left(\operatorname{gr}_{\mathrm{F}}^{\star} \triangle_{R / W(k) \llbracket z_{0} \rrbracket}, \mathrm{gr}_{\mathrm{F}}^{\star} \triangle_{R / W(k)} \llbracket z_{0}, z_{1} \rrbracket\right)$, the element $b$ satisfies $\Delta(b)=$ $b \otimes 1+1 \otimes b$, and admits divided powers. Furthermore, the divided powers $b^{[k]}$ provide a basis of $\operatorname{gr}_{\mathrm{F}}^{\star} \triangle_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}$ as $a \operatorname{gr}_{\mathrm{F}}^{\star} \triangle_{R / W(k)} \llbracket z_{0} \rrbracket$-module.
(ii) In the Hopf algebroid $\left(\operatorname{gr}_{\mathrm{F}}^{\star} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}, \mathrm{gr}_{\mathrm{F}}^{\star} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}\right)$, the element $g_{0}$ satisfies $\Delta\left(g_{0}\right)=g_{0} \otimes 1+1 \otimes g_{0}$, and admits divided powers. Furthermore, the divided powers $g_{0}^{[k]}$ provide a basis of $\operatorname{gr}_{\mathrm{F}}^{\star} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}$ as a $\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}$ module.

Proof. We established that $\Delta\left(g_{0}\right)=g_{0} \otimes 1+1 \otimes g_{0}$ and

$$
\Delta(b)=b \otimes 1+u \otimes b=b \otimes 1+1 \otimes b \quad\left(\bmod \mathrm{~F}^{\geqslant 2} \mathbb{\triangle}_{R / W(k) \llbracket z_{0}, z_{1}, z_{2} \rrbracket}\right)
$$

in Lemmas 4.37 and 4.38. For the statements about divided powers, we first do the Frobenius-twisted case. Recall from Lemma 3.24 that

$$
g_{u}^{p}=\left(-p+d^{p^{u+1}} \lambda_{u}\right) g_{u+1}+d^{p^{u+1}} R_{u}^{\prime}
$$

As $R_{0}^{\prime}=\frac{\delta\left(z_{1}-z_{0}\right)}{\delta(d)}$ and

$$
\delta\left(z_{1}-z_{0}\right)=\frac{z_{1}^{p}-z_{0}^{p}-\left(z_{1}-z_{0}\right)^{p}}{p}=\frac{\left(z_{0}+g_{0}\right)^{p}-z_{0}^{p}-g_{0}^{p}}{p}
$$

we have that $R_{0}^{\prime}$ is divisible by $g_{0}$, so in particular it is a polynomial in the $g_{u}$ without constant term. The explicit formula for $\delta\left(g_{0}\right)$ then shows that $\delta\left(g_{0}\right)$ is a polynomial in the $g_{u}$ without constant term, and then the formula for $R_{1}^{\prime}$ shows that $R_{1}^{\prime}$ is a polynomial in the $g_{u}$ without constant term. Inductively, this shows that all $R_{u}^{\prime}$ and $\delta\left(g_{u}\right)$ are polynomials in the $g_{u}$ without constant terms. So $d^{p^{u+1}-1} R_{u}^{\prime}$ is still in $\mathrm{N} \geqslant p^{u+1} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}$, and we have

$$
g_{u}^{p}=\left(-p+p^{p^{u+1}} \lambda_{u}\right) g_{u+1}+p d^{p^{u+1}-1} R_{u}^{\prime}
$$

in $\operatorname{gr}_{\mathrm{F}}^{p^{u+1}} \mathrm{~N} \geqslant p^{u+1} \widehat{\triangle}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}$. So $g_{u}$ has a $p$ th divided power in the F-associated graded ring (unique because of torsion-freeness), and it agrees with

$$
g_{u}^{[p]}=\left(-1+p^{p^{u+1}-1} \lambda_{u}\right) g_{u+1}+d^{p^{u+1}-1} R_{u}^{\prime} .
$$

As $R_{u}^{\prime}$ is a polynomial in $g_{0}, \ldots, g_{u}$, this equation also proves that $g_{u}^{[p]}$ again has a $p$ th divided power, and we deduce inductively that $g_{0}$ has all divided powers. We also see that $g_{0}^{\left[p^{u}\right]}$ differs from a unit multiple of $g_{u}$ by some polynomial in $g_{0}, \ldots, g_{u-1}$, and so it follows that the $g_{0}^{\left[p^{u}\right]}$ form a basis as claimed.

We obtain the statement for the non-Frobenius twisted version by applying the relative divided Frobenius.

Remark 4.52. Because the relative-to-absolute Hopf algebroid is compatible with the F-filtration and because the associated graded pieces are crystalline prisms, the existence of the divided power structure on the Frobenius twists follows from the crystalline comparison theorem.

Lemma 4.53. If $\left(\Gamma_{0}, \Gamma_{1}\right)$ denotes either the non-Frobenius twisted or Frobenius twisted descent Hopf algebroid and $\theta: \Gamma_{1} \rightarrow \Gamma_{0}$ as in Lemma 4.43, then the sequence

$$
0 \rightarrow \Gamma_{0} \xrightarrow{\eta_{L}} \Gamma_{1} \xrightarrow{\nabla_{\theta}} \Gamma_{1} \rightarrow 0
$$

is F-completely exact.

Proof. It suffices to check this after passage to the F-associated graded. In that case, we let $y=b$ in the non-Frobenius twisted case or $y=g_{0}$ in the Frobenius twisted case, and recall that $y$ is primitive and has divided powers. We have

$$
\Delta\left(y^{[k]}\right)=\sum_{j} y^{[j]} \otimes y^{[k-j]}
$$

and $\theta(y)=1$, and so

$$
\nabla_{\theta}\left(y^{[k]}\right)=y^{[k-1]}+\sum_{k \geqslant 2} y^{[j]} \cdot \theta\left(y^{[k-j]}\right) .
$$

We also have $\theta(1)=0$ and thus $\nabla_{\theta}(1)=0$. Since $\nabla_{\theta}$ on $\Gamma_{1}$ is a left $\Gamma_{0}$ module map, and the above shows that with respect to the $y^{[k]}$-basis it is strictly upper triangular with ones on the first off diagonal, the kernel is precisely $\Gamma_{0} \cdot 1$, as claimed.

Proof of Lemma 4.43. The claim now follows by applying the two-sided coBar construction $\operatorname{coBar}_{\Gamma}(M,-)$ with the trivial right comodule $\Gamma_{0}$ to the short exact sequence from Lemma 4.53. More precisely, consider the map

of complexes, natural in a right $\Gamma$-comodule $M$. It is a quasi-isomorphism if $M$ is of the form $N \otimes_{\Gamma_{0}} \Gamma_{1}$ for a flat right $\Gamma_{0}$-module $N$, since then both complexes are augmented by $N$, and the augmentation is a quasiisomorphism for the top one since the cobar complex for $\Gamma_{1}$ has an extra degeneracy, and for the bottom one cause of Lemma 4.53. Since we may resolve $\Gamma_{0}\{i\}$ as right $\Gamma$-comodule by such induced comodules, the statement then follows for $M=\Gamma_{0}\{i\}$ as well, which is what we wanted to prove.

### 4.8 Properties of $\nabla$

We now analyze compatibility of $\nabla$ with the structure maps. Observe that Lemma 4.43 asserts that $\theta$ determines an isomorphism

$$
\operatorname{ker}\left(\mathrm{F}^{\geqslant \star} \widehat{\triangle}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}\{i\} \rightarrow \mathrm{F}^{\geqslant \star} \widehat{\triangle}_{R / W(k) \llbracket z_{0}, z_{1}, z_{2} \rrbracket}\{i\}\right) \cong \mathrm{F}^{\geqslant \star} \widehat{\Delta}_{R / W(k) \llbracket z_{0} \rrbracket}^{\nabla}\{i\},
$$

and analogously for the Frobenius-twisted version, in which case it is also compatible with the Nygaard filtration (including the shift on the $\nabla$-term).

Definition 4.54. For $R=\mathcal{O}_{K} / \varpi^{n}$ or $\mathcal{O}_{K}$ and the natural structure maps can, $\varphi, \varphi_{R / W(k) \llbracket z_{0} \rrbracket, w \text {, where }}$ $w: \widehat{\mathbb{}}_{R / A} \rightarrow \widehat{\mathbb{}}_{R / A}^{(1)}$ is the canonical $\varphi$-semilinear map, we let

$$
\begin{aligned}
& \operatorname{can}^{\nabla}: \mathrm{F}^{\geqslant \star} \mathrm{N} \geqslant j \widehat{\widehat{\Delta}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} \rightarrow \mathrm{F} \geqslant \star \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\}, \\
& \varphi^{\nabla}: \mathrm{F}^{\geqslant \star} \mathrm{N}^{\geqslant i} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} \rightarrow \mathrm{F} \geqslant p \cdot \star \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\}, \\
& \varphi_{R / W(k) \llbracket z_{0} \rrbracket}^{\nabla}: \mathrm{F}^{\geqslant \star} \mathrm{N}^{\geqslant i} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} \rightarrow \mathrm{F}^{\geqslant \star} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{\nabla}\{i\}, \\
& w^{\nabla}: \mathrm{F}^{\geqslant \star} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{\nabla}\{i\} \rightarrow \mathrm{F}^{\geqslant p \cdot \star} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\}
\end{aligned}
$$

denote the corresponding maps obtained by transporting them along the above isomorphism $\theta$.
Lemma 4.55. For $R=\mathcal{O}_{K} / \varpi^{n}$ or $\mathcal{O}_{K}, \nabla$ commutes with can. In other words, the following diagram commutes:

Proof. The left square commutes by definition. For the right square, commutativity unwinds to the claim that $\theta$ commutes with can, which can be checked on basis elements.

Lemma 4.56. For $R=\mathcal{O}_{K} / \varpi^{n}$ or $\mathcal{O}_{K}$, and $R^{\prime}=\mathcal{O}_{K} / \varpi^{m}$, with $R \rightarrow R^{\prime}$ the reduction map, $\nabla$ commutes with the induced map on prismatic cohomology, i.e., the following diagram commutes:

The analogous statement holds for the Frobenius-twisted version.
Proof. This again reduces to checking that $\theta$ commutes with the induced maps, which follows since it preserves the $\prod g_{u}^{e_{u}}$-basis expressing $\widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, z_{1} \rrbracket}$ as an F-completely free $\widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}$-module.

Lemma 4.57. For $R=\mathcal{O}_{K} / \varpi^{n}$ or $\mathcal{O}_{K}, \nabla$ commutes with the relative Frobenius, i.e., the following diagram commutes:

$$
\begin{aligned}
& \mathrm{F}^{\geqslant \star} \mathrm{N}^{\geqslant i} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \xrightarrow{\nabla} \mathrm{F}^{\geqslant \star} \mathrm{N}^{\geqslant i} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} \Longrightarrow \mathrm{F}^{\geqslant \star} \mathrm{N}^{\geqslant i-1} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i-1\} \\
& \downarrow_{R / W(k) \llbracket z_{0} \rrbracket} \quad \downarrow_{R / W(k) \llbracket z_{0} \rrbracket}^{\nabla} \quad \downarrow \varphi_{R / W(k) \llbracket z_{0} \rrbracket} \\
& \mathrm{~F} \geqslant \star \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}\{i\} \longrightarrow \mathrm{F} \geqslant \star \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}\{i\} \Longrightarrow \mathrm{F} \geqslant \star \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}\{i-1\} .
\end{aligned}
$$

Proof. Again, the left square commutes by definition. For the right square, we again check that $\theta$ commutes with the relative Frobenius, which comes from the fact that the divided Frobenius takes $g_{u} \mapsto \delta^{u} b$, i.e., it respects the monomial bases involved in the definition of $\theta$ on the Frobenius-twisted and the non Frobeniustwisted versions of relative prismatic cohomology.

Remark 4.58. The corresponding statement for the absolute Frobenius (and the canonical map $w: \widehat{\otimes} \rightarrow$ $\left.\widehat{\Delta}^{(1)}\right)$ is false: $\varphi^{\nabla}$ and $w^{\nabla}$ do not agree with $\varphi$ and $w$.

### 4.9 Isogeny properties

In this section, we determine the action of can, $\nabla$ and the map induced by $\mathcal{O}_{K} \rightarrow \mathcal{O}_{K} / \varpi^{n}$ on the F -associated graded. We obtain that various maps are rationally invertible, and explicit formulas for their determinants. We note that these results are very similar in nature to [42] and could in fact be reduced to this using the idea of crystalline degeneration.

Recall that $\operatorname{gr}_{\mathrm{F}}^{j} \widehat{\mathbb{\Delta}}_{\left(\mathcal{O}_{K} / \varpi^{n}\right) / W(k) \llbracket z_{0} \rrbracket}^{(1)}$ is a free $W(k)$-module on a generator $z_{0}^{k} \prod f_{u}^{e_{u}}$ where $\sum p^{u} e_{u}=\left\lfloor\frac{j}{n}\right\rfloor$ with all $e_{u}<p$, and $k$ is the remainder of $j \bmod n$. Similarly, $\mathrm{gr}^{j} \mathrm{~N}_{\mathrm{F}}^{\geqslant i}{\widehat{{ }_{\triangle}^{(O}}}_{\left(\mathcal{O}_{K} / \varpi^{n}\right) / W(k) \llbracket z_{0} \rrbracket}^{(1)}$ is a free $W(k)-$ module on a generator $\widetilde{d}^{l} z_{0}^{k} \prod f_{u}^{e_{u}}$ where $\sum p^{u} e_{u}=\left\lfloor\frac{j}{n}\right\rfloor$ with all $e_{u}<p, k$ is the remainder of $j \bmod n$, and $l=\max \left(i-\sum e_{u} p^{u}, 0\right)$. Analogously, $\operatorname{gr}_{\mathrm{F}}^{k} \widehat{\mathbb{\Delta}}_{\mathcal{O}_{K} / W(k) \llbracket z_{0} \rrbracket}^{(1)}$ and $\operatorname{gr}_{\mathrm{F}}^{k} \mathrm{~N}^{\geqslant i} \widehat{\triangle}_{\mathcal{O}_{K} / W(k) \llbracket z_{0} \rrbracket}^{(1)}$ are free on $z_{0}^{k}$ and $\widetilde{d}^{i} z_{0}^{k}$ respectively. Generators for the Breuil-Kisin twisted terms are obtained by formally multiplying with the orientation $w\left(s^{i}\right)$. On the $\nabla$-terms, we have the same generators with a shift in indexing.

Lemma 4.59. For $R=\mathcal{O}_{K} / \varpi^{n}$, the can and can ${ }^{\nabla}$ maps are described on the F -associated graded as follows with respect to the chosen bases:

$$
\begin{equation*}
\operatorname{gr}_{\mathrm{F}}^{j} \mathrm{~N}^{\geqslant i} \widehat{\Delta}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)} \rightarrow \operatorname{gr}_{\mathrm{F}}^{j} \mathrm{~N} \geqslant i \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)} \tag{1}
\end{equation*}
$$

is multiplication with $p^{\max \left(i-\left\lfloor\frac{j}{n}\right\rfloor, 0\right)}$;
(2)

$$
\operatorname{gr}_{\mathrm{F}}^{j} \mathrm{~N}^{\geqslant i} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla} \rightarrow \operatorname{gr}_{\mathrm{F}}^{j} \mathrm{~N}^{\geqslant i} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}
$$

is multiplication with $p^{\max \left(i-1-\left\lfloor\frac{j-1}{n}\right\rfloor, 0\right)}$.
The analogous statements hold with Breuil-Kisin twists.
Proof. For the first statement, the basis element is $\widetilde{d}^{l} z_{0}^{k} \prod f_{u}^{e_{u}}$ with $l=\max \left(i-\sum p^{u} e_{u}, 0\right), \sum p^{u} e_{u}=\left\lfloor\frac{j}{n}\right\rfloor$, and $k$ the residue of $j \bmod n$. Since the basis element in the target is $z_{0}^{k} \prod f_{u}^{e_{u}}$ and $\widetilde{d}=E\left(z_{0}\right)$ is $p$ in the F-associated graded, the claim follows.

The second statement follows from the first by taking into account the indexing shift from the definition of the target of $\nabla$.

Lemma 4.60. The reduction maps induced by $\mathcal{O}_{K} \rightarrow \mathcal{O}_{K / \varpi^{n}}$ are described on the F -associated graded as follows with respect to the chosen bases:

$$
\begin{equation*}
\operatorname{gr}_{\mathrm{F}}^{j} \widehat{\Delta}_{\mathcal{O}_{K} / W(k) \llbracket z_{0} \rrbracket}^{(1)} \rightarrow \operatorname{gr}_{\mathrm{F}}^{j} \widehat{\triangle}_{\left(\mathcal{O}_{K} / \varpi^{n}\right) / W(k) \llbracket z_{0} \rrbracket}^{(1)} \tag{1}
\end{equation*}
$$

is multiplication with a unit multiple of $\left\lfloor\frac{j}{n}\right\rfloor!$ and

$$
\begin{equation*}
\operatorname{gr}_{\mathrm{F}}^{j} \widehat{\mathbb{\Delta}}_{\mathcal{O}_{K} / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla} \rightarrow \operatorname{gr}_{\mathrm{F}}^{j} \widehat{\triangle}_{\left(\mathcal{O}_{K} / \varpi^{n}\right) / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla} \tag{2}
\end{equation*}
$$

is multiplication with a unit multiple of $\left\lfloor\frac{j-1}{n}\right\rfloor!$..
The analogous statements hold with Breuil-Kisin twists.
Proof. On the F-associated graded, $d=p$, and so $f_{u}^{p}=\left(-p+\lambda_{u} p^{p^{u+1}} f_{u+1}\right)$. This exhibits $f_{u}^{p}$ as unit multiple of $p f_{u+1}$, so $z_{0}^{n}=f_{0}$ has all divided powers, and the basis monomials $f_{u}^{e_{u}}$ are unit multiples of the divided powers $\left(z_{0}^{n}\right)^{[s]}$. It follows that $z_{0}^{j}$ is taken to $z_{0}^{k} s!\left(z_{0}^{n}\right)^{[s]}$ where $k$ is the remainder of $j$ modulo $n$ and $s=\left\lfloor\frac{j}{n}\right\rfloor$. The second statement follows from the first by taking into account the indexing shift from the definition of the target of $\nabla$.

Lemma 4.61. For $\mathcal{O}_{K}$, the map $\nabla$ acts on the F -associated graded with respect to the chosen bases as follows:
(1)

$$
\nabla: \operatorname{gr}_{\mathrm{F}}^{j} \widehat{\widehat{\Delta}}_{\mathcal{O}_{K} / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \operatorname{gr}_{\mathrm{F}^{j}}^{j} \widehat{\mathbb{\Delta}}_{\mathcal{O}_{K} / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\}
$$

acts by multiplication with a unit multiple of $j$ and

$$
\begin{equation*}
\nabla: \operatorname{gr}_{\mathrm{F}}^{j} \mathrm{~N}^{\geqslant i} \widehat{\triangle}_{\mathcal{O}_{K} / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \operatorname{gr}_{\mathrm{F}}^{j} \mathrm{~N}^{\geqslant i} \widehat{\triangle}_{\mathcal{O}_{K} / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} \tag{2}
\end{equation*}
$$

for $i \geqslant 1$ acts by multiplication with a unit multiple of $p^{\epsilon(i, j)} j$, where

$$
\epsilon=\left\{\begin{array}{l}
1 \text { if }\left\lfloor\frac{j}{n}\right\rfloor<\left\lceil\frac{j}{n}\right\rceil \leqslant i \\
0 \text { otherwise }
\end{array}\right.
$$

Proof. We have

$$
\nabla\left(z_{0}^{j} w\left(s^{i}\right)\right)=\theta\left(\left(\left(z_{0}+g_{0}\right)^{j} w\left(v^{i}\right)-z_{0}^{j}\right) w\left(s^{i}\right)\right)
$$

i.e. $w\left(s^{i-1}\right)$ times the coefficient of $g_{0}$ in $\left(z_{0}+g_{0}\right)^{j} w\left(v^{i}\right)-z_{0}^{j}$. Working in the F-associated graded, the unit $v$ is 1 , so

$$
\nabla\left(z_{0}^{j} w\left(s^{i}\right)\right)=j z_{0}^{j-1} w\left(s^{i-1}\right)+\sum_{m=2}^{j}\binom{j}{m} z_{0}^{j-m} \theta\left(g_{0}^{m} s_{i}\right)
$$

For weight reasons, each of the summands is a multiple of $z_{0}^{j-1}$. As observed in Lemma 4.51, $g_{0}$ has divided powers. So each of the summands for $m \geqslant 2$ is divisible by $\binom{j}{m} m!$. By Kummer's theorem, this has $p$-valuation at least

$$
v_{p}(j)-v_{p}(m)+v_{p}(m!)
$$

which is strictly bigger than $v_{p}(j)$ unless $m=2$. If $p \neq 2, \theta\left(g_{0}^{2} s^{i}\right)=0$. If $p=2$, we deduce that $\theta\left(g_{0}^{2} w\left(s^{i}\right)\right)$ is divisible by $d^{2}$ since

$$
g_{0}^{2}=\left(-2+\lambda_{0} d^{2}\right) g_{1}+d^{2} R_{0}^{\prime}
$$

and since $d=p$ in the F-associated graded we conclude in all cases that each of the $m \geqslant 2$ summands is divisible by $p j z_{0}^{j-1} w\left(s^{i-1}\right)$. So we conclude that $\nabla\left(z_{0}^{j} w\left(s^{i}\right)\right)$ is a unit multiple of $j z_{0}^{j-1} w\left(s^{i-1}\right)$.

For the second statement, we use the commutative square

observing that, up to units, the bottom horizontal map acts by $j$, the left vertical map acts by $p^{\max \left(i-\left\lfloor\frac{j}{n}\right\rfloor, 0\right)}$, and the right vertical map acts by $p^{\max \left(i-1-\left\lfloor\frac{j-1}{n}\right\rfloor, 0\right)}$. The difference of these exponents is at most 1 , and only is 1 if $i>\left\lfloor\frac{j}{n}\right\rfloor$ and $i-\left\lfloor\frac{j}{n}\right\rfloor>i-1-\left\lfloor\frac{j-1}{n}\right\rfloor$. This happens if and only if $j$ is not divisible by $n$ and $\left\lceil\frac{j}{n}\right\rceil \leqslant i$, i.e. if $\epsilon(i, j) \neq 1$. So the above diagram shows that the top horizontal map acts by a unit multiple of $p^{\epsilon(i, j)} j$.

Lemma 4.62. For $R=\mathcal{O}_{K} / \varpi^{n}$, the map $\nabla$ acts on the F -associated graded with respect to the chosen bases as follows:

$$
\begin{equation*}
\nabla: \operatorname{gr}_{\mathrm{F}}^{j} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \operatorname{gr}_{\mathrm{F}}^{j} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} \tag{1}
\end{equation*}
$$

acts by multiplication with a unit multiple of $\{j, n\}$, where

$$
\{j, n\}=\left\{\begin{array}{l}
n \text { if } n \mid j \\
j \text { otherwise }
\end{array}\right.
$$

(2)

$$
\nabla: \operatorname{gr}_{\mathrm{F}}^{j} \mathrm{~N}^{\geqslant i} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \operatorname{gr}_{\mathrm{F}}^{j} \mathrm{~N}^{\geqslant i} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\}
$$

for $i \geqslant 1$ acts by multiplication with a unit multiple of $p^{\epsilon(i, j)}\{j, n\}$.
Proof. We use the commutative diagram

The top horizontal map acts by multiplication with a unit multiple of $j$. The left vertical map acts by $\left\lfloor\frac{j}{n}\right\rfloor!$, and the right vertical map by $\left\lfloor\frac{j-1}{n}\right\rfloor$ ! due to the indexing shift. We obtain that the bottom map acts by a unit multiple of

$$
j \cdot\left\lfloor\frac{j-1}{n}\right\rfloor!\cdot\left(\left\lfloor\frac{j}{n}\right\rfloor!\right)^{-1}
$$

The quotient of the two factorial terms is 1 if $n \nmid j$, and $\left(\frac{j}{n}\right)^{-1}$ if $n \mid j$. In total we obtain that the bottom map acts by a unit multiple of $\{j, n\}$ as claimed.

For the second statement, we proceed analogously with $N \geqslant i \widehat{\Delta}^{(1)}$.

In particular, we may conclude from this that all maps in the syntomic square as well as the reduction maps are rational isomorphisms on any finite part $\mathrm{F}^{[a, b]}$ of the F-filtration:

Lemma 4.63. For $R=\mathcal{O}_{K} / \varpi^{n}$ or $R=\mathcal{O}_{K}$, the map

$$
\text { can: } \mathrm{N} \geqslant i \widehat{\triangle}_{R / W(k) \llbracket z_{0}, \ldots, z_{s} \rrbracket}^{(1)}\{i\} \rightarrow \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0}, \ldots, z_{s} \rrbracket}^{(1)}\{i\}
$$

is a rational isomorphism on $\mathrm{F}^{[a, b]}$ for any integers $a \leqslant b$. Its cokernel has order

$$
\prod_{j=a}^{\min (b, i n-1)} q^{i-\left\lfloor\frac{j}{n}\right\rfloor}
$$

where $q=p^{f}$ is the order of the residue field $k$.
Proof. This follows directly from the description of can on the F-associated graded.
Lemma 4.64. The reduction map

$$
\text { red : } \widehat{\mathbb{\Delta}}_{\mathcal{O}_{K} / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \widehat{\mathbb{}}_{\left(\mathcal{O}_{K} / \varpi^{n}\right) / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\}
$$

is a rational isomorphism on $\mathrm{F}^{[a, b]}$ for any integers $a \leqslant b$. Its cokernel has order $\prod_{j=a}^{b} q^{v_{p}\left(\left\lfloor\frac{j}{n}\right\rfloor!\right)}$.
Proof. This follows directly from the description of red on the F-associated graded.

## Lemma 4.65.

(1) For $R=\mathcal{O}_{K} / \varpi^{n}$ or $\mathcal{O}_{K}$, the map

$$
\nabla: \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\}
$$

is a rational isomorphism on $\mathrm{F}^{[a, b]}$ for any integers $a \leqslant b$ with $a \geqslant 1$. Its cokernel has order $\prod_{j=a}^{b} q^{v_{p}\{j, n\}}$ for $R=\mathcal{O}_{K} / \varpi^{n}$ and $\prod_{j=a}^{b} q^{j}$ for $R=\mathcal{O}_{K}$.
(2) For $R=\mathcal{O}_{K} / \varpi^{n}$ or $\mathcal{O}_{K}$ and $i \geqslant 1$, the map

$$
\nabla: \mathrm{N}^{\geqslant i} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \mathrm{N}^{\geqslant i} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\}
$$

is a rational isomorphism on $\mathrm{F}^{[a, b]}$ for any integers $a \leqslant b$ with $a \geqslant 1$. Its cokernel has order $\prod_{j=a}^{b} q^{\epsilon(i, j)+v_{p}\{j, n\}}$ for $R=\mathcal{O}_{K} / \varpi^{n}$ and $\prod_{j=a}^{b} q^{\epsilon(i, j)+v_{p}(j)}$ for $R=\mathcal{O}_{K}$.

Proof. This follows directly from the description of $\nabla$ on the F-associated graded.
Remark 4.66. Lemma 4.65 can be used to derive the Angeltveit quotient result of Proposition 2.18.
Remark 4.67. These results together imply the following for the structure maps on $\mathrm{F}^{[a, b]}$, with $a \geqslant 1$.
(1) From knowledge of the map

$$
\nabla: \mathrm{F}^{[a, b]} \widehat{\mathbb{}}_{\mathcal{O}_{K} / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \mathrm{F}^{[a, b]} \widehat{\mathbb{}}_{\mathcal{O}_{K} / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\}
$$

and the maps induced by the reduction $\mathcal{O}_{K} \rightarrow \mathcal{O}_{K} / \varpi^{n}$, we may recover the map

$$
\nabla: \mathrm{F}^{[a, b]} \widehat{\mathbb{\Delta}}_{\left(\mathcal{O}_{K} / \varpi^{n}\right) / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \mathrm{F}^{[a, b]} \widehat{\mathbb{}}_{\left(\mathcal{O}_{K} / \varpi^{n}\right) / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\}
$$

(analogously for the non-Frobenius twisted version).
(2) From knowledge of the map
and the can maps, we may recover the map

$$
\nabla: \mathrm{F}^{[a, b]} \mathrm{N} \geqslant i \widehat{\Delta}_{\left(\mathcal{O}_{K} / \omega^{n}\right) / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \mathrm{F}^{[a, b]} \mathrm{N} \geqslant \widehat{\widehat{\Delta}}_{\left(\mathcal{O}_{K} / \omega^{n}\right) / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla^{2}}\{i\} .
$$

(3) From knowledge of the maps

$$
\begin{aligned}
& \nabla: \mathrm{F}^{[a, b]} \widehat{\Delta}_{\left(\mathcal{O}_{K} / \varpi^{n}\right) / W(k)[z]}^{(1)}\{i\} \rightarrow \mathrm{F}^{[a, b]} \widehat{\mathbb{\Delta}}_{\left(\mathcal{O}_{K} / \omega^{n}\right) / W(k)\left[z_{0}\right]}\{i\}, \\
& \nabla: \mathrm{F}^{[a, b]} \mathrm{N} \geqslant i \widehat{\Delta}_{\left(\mathcal{O}_{K} / \varpi^{n}\right) / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \mathrm{F}^{[a, b]} \mathrm{N} \geqslant i \widehat{\Delta}_{\left.\left(\mathcal{O}_{K} / \varpi^{n}\right) / W(k) \llbracket z_{0}\right]}^{(1), \nabla}\{i\},
\end{aligned}
$$

and the Frobenius map
we may recover the map $\varphi^{\nabla}$.
So in practice, all structure maps appearing in the syntomic square (Corollary 4.44) are determined by the can and $\varphi$ maps for $\mathcal{O}_{K} / \varpi^{n}$, the reduction map for $\mathcal{O}_{K} \rightarrow \mathcal{O}_{K} / \varpi^{n}$, and the map $\nabla$ for $\mathcal{O}_{K}$. One advantage is that the latter depends on $\mathcal{O}_{K}$ and the choice of uniformizer, but not on $n$. The other advantage is that each of these pieces of data requires computations in $\widehat{\mathbb{\Delta}}_{\left(\mathcal{O}_{K} / \omega^{n}\right) / W(k) \llbracket z_{0} \rrbracket}^{(1)}$ or $\widehat{\mathbb{}}_{\mathcal{O}_{K} / W(k) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}$, but never $\widehat{\mathbb{\Delta}}_{\left(\mathcal{O}_{K} / \varpi^{n}\right) / W(k) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}$, which is significantly bigger.

## 5 The even vanishing theorem

In this section, we prove the following fact: $\mathrm{K}_{2 i-2}\left(\mathcal{O} / \varpi^{n}\right)$ vanishes for $i \gg 0$. This comes as a complete surprise, since, in the previously known range of $\mathrm{K}_{*}\left(\mathbf{Z} / p^{n}\right)$ due to Angeltveit [2], while $\mathrm{K}_{2 i-2}\left(\mathbf{Z} / p^{n}\right)=0$ for all $2 \leqslant i<p$, one has $\mathrm{K}_{2 p-2}\left(\mathbf{Z} / p^{n}\right) \cong \mathbf{Z} / p$. In the characteristic $p$ case, where $\mathcal{O}_{K} / \varpi^{n} \cong \mathbf{F}_{p}[z] / z^{n}$, the even degree positive K-groups all vanish due to a result of Hesselholt-Madsen (see Corollary 5.5, which we can obtain as a special case of Theorem 5.2). Note that the vanishing of the even degree K-groups in sufficiently large degrees determines the orders of the odd degree K-groups in sufficiently large degrees by Proposition 2.18.

Definition 5.1 ( $p$-analogues). Recall that the $p$-analogue of an integer $j$ is

$$
[j]_{p}=\frac{p^{j}-1}{p-1}=1+p+p^{2}+\cdots+p^{j-1} .
$$

Theorem 5.2. If

$$
i-1 \geqslant \frac{p}{p-1}\left(p[j]_{p}-p^{j} j+p^{j} \frac{n}{e}\right)
$$

with $j=\left\lceil\frac{n}{e}\right\rceil$, then $\mathrm{K}_{2 i-2}\left(\mathcal{O}_{K} / \varpi^{n}\right)=0$.
Remark 5.3. The number $j=\left\lceil\frac{n}{e}\right\rceil$ is the exponent of the abelian group $\mathcal{O}_{K} / \varpi^{n}$.
Remark 5.4. As $\frac{n}{e}-j \leqslant 0$, a slightly weaker but cleaner bound is given by

$$
i-1 \geqslant \frac{p}{p-1} \cdot p[j]_{p}=\frac{p^{2}}{(p-1)^{2}} \cdot\left(p^{j}-1\right)
$$

This version has the same asymptotic behaviour, but does not imply Corollary 5.5 below.
The following corollary was originally discovered in [25, Thm. A].

Corollary 5.5 (Hesselholt-Madsen). For all $i \geqslant 2$,

$$
\mathrm{K}_{2 i-2}\left(\mathbf{F}_{q}[z] / z^{n}\right)=0
$$

Proof. We can write $\mathbf{F}_{q}[z] / z^{n}$ as a quotient of rings of the form $\mathcal{O}_{K}$ where $K$ has arbitrarily large ramification index $e$; for example $\mathbf{F}_{q}[z] / z^{n} \cong W\left(\mathbf{F}_{q}\right)\left[p^{1 / e}\right] / p^{n / e}$. Thus, we can choose $e$ arbitrarily large in Theorem 5.2. For large $e$, we have $j=1$ and the inequality simplifies to

$$
i-1 \geqslant \frac{p^{2} n}{(p-1) e}
$$

which is satisfied for any $i \geqslant 2$ for $e$ sufficiently large.
Corollary 5.6. If

$$
i-1 \geqslant \frac{p}{p-1}\left(p[j]_{p}-p^{j} j+p^{j} \frac{n}{e}\right)
$$

with $j=\left\lceil\frac{n}{e}\right\rceil$, then $\mathrm{K}_{2 i-1}\left(\mathcal{O}_{K} / \varpi^{n}\right)$ is a group of order $\left(q^{i}-1\right) \cdot q^{i(n-1)}$, where $q$ is the order of the residue field of $\mathcal{O}_{K}$.
Proof. This follows from Theorem 5.2, Proposition 2.18, Corollary 2.3, and Quillen's calculation in [37] of the K-theory of finite fields.

### 5.1 Nilpotency $\bmod p$

In this section, we observe that in $\widehat{\triangle}_{R / W(k) \llbracket z \rrbracket}^{(1)}$ and $\mathrm{N} \geqslant * \widehat{\triangle}_{R / W(k) \llbracket z \rrbracket}^{(1)}$ for $R=\mathcal{O}_{K} / \varpi^{n}$, various elements become nilpotent mod $p$. This will feature in our proof of the even vanishing theorem, but also implies nilpotence of $v_{1}$. It also implies that, in large F-filtration, the prismatic envelope $\widehat{\triangle}_{R / W(k) \llbracket z \rrbracket}^{(1)}$ admits divided powers.

Below, we write $x \sim y$ for two elements which are unit multiples mod $p$. Recall that

$$
f_{u}^{p} \sim d^{p^{u+1}} f_{u+1} \sim z^{e p^{u+1}} f_{u+1}
$$

in $\mathrm{N} \geqslant p^{u+1} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}$. This follows from the explicit relation for $f_{u}^{p}$ given in Lemma 3.24, the fact that the $R_{u}^{\prime}$ vanish for the relation $z^{n}$ by Remark 3.29, and the fact that $d=E(z) \sim z^{e}$.
Lemma 5.7. Let $R=\mathcal{O}_{K} / \varpi^{n}$. In $\mathrm{N}^{p^{j-1}-1} \widehat{\triangle}_{R / W(k) \llbracket z \rrbracket}^{(1)}$ for $j \leqslant\left\lceil\frac{n}{e}\right\rceil$, we have

$$
z^{p^{j-1}(n-j e)+[j]_{p} e-1} d^{p^{j-1}-1} \sim z^{n-1} f_{0}^{p-1} \cdots f_{j-2}^{p-1}
$$

Proof. For $j=1$, this is the tautology $z^{n-1}=z^{n-1}$. We now proceed by induction. Assuming the relation for $j<\frac{n}{e}$, first observe that

$$
z^{p^{j-1}(n-j e)+[j]_{p} e-1} d^{p^{j-1}} \sim z^{n-1} f_{0}^{p-1} \cdots f_{j-2}^{p-1} d
$$

Multiplying both sides with $z$ and using $z^{n} d \sim z^{e} f_{0}$ and $f_{u}^{p} \sim z^{e p^{u+1}} f_{u+1}$, we learn that

$$
z^{p^{j-1}(n-j e)+[j]_{p} e} d^{p^{j-1}} \sim z^{[j]_{p} e} f_{j-1}
$$

As $n-j e>0$, we may use this relation $p-1$ times to deduce that

$$
z^{(p-1) p^{j-1}(n-j e)+[j]_{p} e} d^{p^{j}-1} \sim z^{[j]_{p} e} f_{j-1}^{p-1} d^{p^{j-1}-1}
$$

(note that the exponent on the left-hand side is $p^{j}-1$, not $p^{j-1}$ ). Finally, multiplying with $z^{p^{j-1}(n-j e)-1}$ and using the inductive assumption once more, we obtain

$$
z^{p^{j}(n-j e)+[j]_{p} e-1} d^{p^{j}-1} \sim z^{n-1} f_{0}^{p-1} \cdots f_{j-1}^{p-1}
$$

Since $p^{j}(n-j e)+[j]_{p} e-1=p^{j}(n-(j+1) e)+[j+1]_{p} e-1$, this completes the inductive step.

Lemma 5.8. Let $R=\mathcal{O}_{K} / \varpi^{n}$. In $\widehat{\mathbb{}}_{R / W(k) \llbracket z \rrbracket}^{(1)}$ for $j \leqslant\left\lceil\frac{n}{e}\right\rceil$, we have

$$
z^{p^{j}(n-j e)+p[j]_{p} e-1} \sim z^{n-1} f_{0}^{p-1} \cdots f_{j-1}^{p-1}
$$

Proof. The $j<\left\lceil\frac{n}{e}\right\rceil$ case can be deduced directly from Lemma 5.7, but the $j=\left\lceil\frac{n}{e}\right\rceil$ case requires special manipulations either way, so we proceed by an analogous induction. For $j=0$, we again have the tautology $z^{n-1}=z^{n-1}$. Given the relation for some $j<\frac{n}{e}$, multiplication by $z$ yields

$$
\begin{equation*}
z^{p^{j}(n-j e)+p[j]_{p} e} \sim z^{p[j]_{p} e} f_{j} \tag{15}
\end{equation*}
$$

As $n-j e>0$, we may multiply (15) with $z^{(p-2) p^{j}(n-j e)}$ and simplify using the relation (15) to obtain

$$
\begin{equation*}
z^{(p-1) p^{j}(n-j e)+p[j]_{p} e} \sim z^{p[j]_{p} e} f_{j}^{p-1} \tag{16}
\end{equation*}
$$

Multiplying (16) with $z^{p^{j}(n-j e)-1}$ and using the inductive assumption yields the relation

$$
z^{p^{j+1}(n-j e)+p[j]_{p} e-1} \sim z^{n-1} f_{0}^{p-1} \cdots f_{j}^{p-1}
$$

As $p^{j+1}(n-j e)+p[j]_{p} e-1=p^{j+1}(n-(j+1) e)+p[j+1]_{p} e-1$, this completes the induction.
Lemma 5.9. Let $R=\mathcal{O}_{K} / \varpi^{n}$ with $n \geqslant 2$. For $j=\left\lceil\frac{n}{e}\right\rceil$,
(1) $z^{p[j]_{p} e-p^{j}(j e-n)}=0$ in $\widehat{\mathbb{}}_{R / W(k) \llbracket z \rrbracket}^{(1)} / p$, but $z^{p[j]_{p} e-p^{j}(j e-n)-1} \neq 0$;
(2) for any $i \geqslant p^{j}-1$,

$$
\text { in } \mathrm{N} \geqslant i \widehat{\triangle}_{R / W(k) \llbracket z \rrbracket}^{(1)} / p \text {, but } z^{[j]_{p} e-p^{j-1}(j e-n)-1} d^{i} \neq 0
$$

Proof. We start with the relation

$$
z^{p^{j}(n-j e)+p[j]_{p} e-1} \sim z^{n-1} f_{0}^{p-1} \cdots f_{j-1}^{p-1}
$$

from Lemma 5.8; these terms are not zero mod $p$ since the right-hand term is one of our standard basis elements of the prismatic cohomology. Multiplying with $z$, we get

$$
z^{p[j]_{p} e-p^{j}(j e-n)} \sim z^{p[j]_{p} e} f_{j} .
$$

As $j e-n \geqslant 0$, the exponent on the right is at least as big as on the left. Thus we may iterate, obtaining elements of arbitrarily high Nygaard filtration. This proves the first statement.

For the second statement, it suffices to treat $i=p^{j}-1$. We start with the relation

$$
z^{p^{j-1}(n-j e)+[j]_{p} e-1} d^{p^{j-1}} \sim z^{n-1} f_{0}^{p-1} \cdots f_{j-2}^{p-1} d
$$

in $\mathrm{N} \geqslant p^{j-1} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}$ implied by Lemma 5.7. The right-hand side of this relation is non-zero as it is one of the standard basis elements of the Nygaard filtration (see Proposition 3.34). Multiplying with $z$, we obtain

$$
z^{[j]_{p} e-p^{j-1}(j e-n)} d^{p^{j-1}} \sim z^{[j]_{p} e} f_{j-1}
$$

As $j e-n \geqslant 0$, we may iterate this to obtain

$$
z^{[j]_{p} e-p^{j-1}(j e-n)} d^{p^{j}-1} \sim z^{[j]_{p} e+(p-2) p^{j-1}(j e-n)} f_{j-1}^{p-1} d^{p^{j-1}-1}
$$

Again, using the relation from Lemma 5.7, we further learn

$$
z^{[j]_{p} e-p^{j-1}(j e-n)} d^{p^{j}-1} \sim z^{(p-1) p^{j-1}(j e-n)+1} z^{n-1} f_{0}^{p-1} \cdots f_{j-1}^{p-1}
$$

The right hand side is a multiple of

$$
z^{n} f_{0}^{p-1} \cdots f_{j-1}^{p-1} \sim z^{p[j]_{p e}} f_{j}
$$

which is zero $\bmod p$ by the first statement.

Corollary 5.10. For $j \geqslant\left\lceil\frac{n}{e}\right\rceil$, the element $f_{j}^{p}$ agrees with $p f_{j+1}$ up to a unit.
Proof. Recall that $f_{j}^{p}=\left(-p+\lambda_{j} d^{p^{j+1}}\right) f_{j+1}$ where $\lambda_{j}$ is some unit. We have that

$$
e\left(p^{j+1}-1\right) \geqslant e p[j]_{p}
$$

and so

$$
d^{p^{j+1}-1} \sim z^{e\left(p^{j+1}-1\right)} \sim 0
$$

by Lemma $5.9(1)$. It follows that $d^{p^{j+1}-1}=0$ modulo $p$, and thus

$$
f_{j}^{p}=\left(-1+\lambda_{j} r d\right) p f_{j+1}
$$

for some $r$. By $d$-completeness, the factor $\left(-1+\lambda_{j} r d\right)$ is a unit.
Remark 5.11. Corollary 5.10 says that "asymptotically" $\widehat{\mathbb{~}}_{\left(\mathcal{O}_{K} / \varpi^{n}\right) / W(k) \llbracket z \rrbracket}^{(1)}$ looks like a free divided power algebra.

### 5.2 A prismatic Cartier isomorphism

Observe the following immediate consequence of relative-to-absolute descent (Corollary 4.44).
Theorem 5.12. The commutative square

induces a quasi-isomorphism between the rows.
Proof. This is due to the fact that both horizontal fibers are $\widehat{\triangle}_{R / \mathbf{Z}_{p}}$ and the canonical inclusion $\widehat{\triangle}_{R / \mathbf{z}_{p}} \rightarrow$ $\widehat{\mathbb{}}_{R / \mathbf{Z}_{p}}^{(1)}$ is an isomorphism since $\mathbf{Z}_{p}$ is perfect.

Remark 5.13. We view this as a kind of Cartier isomorphism, since it looks formally similar to the Cartier isomorphism for $k[z]$ as quasi-isomorphism between the rows of

where the vertical maps are induced by the Frobenius on $k[z]$. (See for example [18].) A meaningful justification of this analogy would require a more conceptual understanding of the connection $\nabla$.

Remark 5.14. Note that the vertical maps take $\mathrm{F} \geqslant j \rightarrow \mathrm{~F} \geqslant p j$, due to the semilinearity of $w$. It follows in particular that $w$ induces an equivalence between the cokernel of

$$
\nabla: \operatorname{gr}_{\mathrm{F}}^{j} \triangle_{R / W(k) \llbracket z_{0} \rrbracket}\{i\} \rightarrow \operatorname{gr}_{\mathrm{F}}^{j} \triangle_{R / W(k) \llbracket z_{0} \rrbracket}^{\nabla}\{i\}
$$

and that of

$$
\nabla: \operatorname{gr}_{\mathrm{F}}^{p j} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \operatorname{gr}_{\mathrm{F}}^{p j} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\},
$$

and that

$$
\nabla: \operatorname{gr}_{\mathrm{F}}^{j} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \operatorname{gr}_{\mathrm{F}}^{j} \widehat{\Delta}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\}
$$

is an isomorphism if $p \nmid j$.

Lemma 5.15. In the case $R=\mathcal{O}_{K} / \varpi^{n}$, the prismatic Cartier isomorphism fits into a commutative diagram

inducing quasi-isomorphisms between the rows whenever $b \leqslant n(i+1)-1$.
Proof. The statement about the lower two rows follows from the fact that the prismatic Cartier isomorphism of Theorem 5.12 is compatible with filtrations. Commutativity of the upper square follows from Lemma 4.57. Recall that $\mathrm{F}^{[1, b]} \triangle_{R / W(k) \llbracket z \rrbracket}$ is a free $W(k)$-module on monomials $z_{0}^{c} \prod \delta^{u}(a)^{e_{u}} s^{i}$ with $c<n, e_{u}<p$ and total filtration $\leqslant b$. Similarly, $\mathrm{F}^{[1, b]} \mathrm{N}^{\geqslant i} \triangle_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}$ is free on monomials $d^{i-\sum p^{u} e_{u}} z_{0}^{c} \prod f_{u}^{e_{u}} w\left(s^{i}\right)$ with total filtration $\leqslant b$. The bound $b \leqslant n(i+1)-1$ guarantees that the $i$ th divided Frobenius sends generators to generators: by construction, and Corollary 3.23,

$$
\varphi_{W(k) \llbracket z_{0} \rrbracket}\left(d^{i-\sum p^{u} e_{u}} z_{0}^{c} \prod f_{u}^{e_{u}} w\left(s^{i}\right)\right)=z_{0}^{c} d^{i} \prod \varphi_{p^{u}}\left(f_{u}\right)^{e_{u}} \frac{s^{i}}{d^{i}}=z_{0}^{c} \prod \delta^{u}(a)^{e_{u}} s^{i},
$$

so the upper left vertical map is an isomorphism. Similarly, the upper right vertical map is an isomorphism and hence the upper square induces a quasi-isomorphism between the top two rows.

### 5.3 Proof of the even vanishing theorem

Lemma 5.16. Let $R=\mathcal{O}_{K} / \varpi^{n}$ and fix $b \geqslant 1$. If

$$
e\left(i-\left\lfloor\frac{b}{n}\right\rfloor\right) \geqslant p[j]_{p} e-p^{j}(j e-n)
$$

with $j=\left\lceil\frac{n}{e}\right\rceil$, then

$$
\text { can: } \mathrm{F}^{[0, b]} \mathrm{N} \geqslant i \widehat{\Delta}_{R / W(k) \llbracket\left[z_{0}\right]}^{(1)}\{i\} \rightarrow \mathrm{F}^{[0, b]} \widehat{\Delta}_{R / W(k) \llbracket\left[z_{0}\right]}^{(1)}\{i\}
$$

is divisible by $p$. Similarly, if

$$
e\left(i-1-\left\lfloor\frac{b}{n}\right\rfloor\right) \geqslant p[j]_{p} e-p^{j}(j e-n)
$$

then

$$
\text { can: } \mathrm{F}^{[1, b+1]} \mathrm{N} \geqslant i \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} \rightarrow \mathrm{F}^{[1, b+1]} \widehat{\triangle}_{\left.R / W(k) \llbracket z_{0}\right]}^{(1), \nabla}\{i\}
$$

is divisible by $p$.
Proof. We may assume $i=0$. A basis for $\mathrm{F}^{[0, b]} \mathrm{N} \geqslant i \widehat{\Delta}_{\left.R / W(k) \llbracket z_{0}\right]}^{(1)}$ is given by $\widetilde{d}^{i-\sum p^{u} e_{u}} z^{k} \Pi f_{u}^{e_{u}}$ with $e_{u}<p$ and $k<n$. Here, $k+\sum n p^{u} e_{u} \leqslant b$, and so the exponent of $d$ is $\geqslant i-\left\lfloor\frac{b}{n}\right\rfloor$. By Lemma 5.9, we have

$$
z^{p[j]_{p e-} p^{j}(j e-n)}=0
$$

$\bmod p$. As $d \sim z^{e}$, the claim follows. The claim for the $\nabla$-term follows from the observation that

$$
\mathrm{F}^{[1, b+1]} \mathrm{N} \geqslant i \widehat{凶}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla} \cong \mathrm{F}^{[0, b]} \mathrm{N} \geqslant i-1 \widehat{\Perp}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)},
$$

compatibly with can.

Proof of Theorem 5.2. It is enough to show that the maps into the lower right corner in the diagram
are jointly surjective. In fact, on the $\nabla$ terms, can is already an isomorphism on $\mathrm{F} \geqslant(i-1) n+1$, and so we may pass to the quasi-isomorphic quotient

$$
\begin{aligned}
& \mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \xrightarrow{\nabla} \mathrm{F}^{[1,(i-1) n]} \mathrm{N}^{\geqslant i} \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} \\
& \downarrow^{\operatorname{can}-\varphi} \quad \downarrow \operatorname{can-\varphi ^{\nabla }} \\
& \mathrm{F}^{[1, i n-1]} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \xrightarrow{\nabla} \mathrm{F}^{[1,(i-1) n]} \widehat{\mathbb{\Delta}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} .
\end{aligned}
$$

Joint surjectivity of the maps into the bottom right corner is equivalent to surjectivity of

$$
\left(\operatorname{can}-\varphi^{\nabla}\right): \mathrm{F}^{[1,(i-1) n]} \mathrm{N} \geqslant i \widehat{\mathbb{\Delta}}_{R / \mathbf{Z}_{p} \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} \rightarrow \mathrm{F}^{[1,(i-1) n]} \widehat{凶}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} / \mathrm{im}(\nabla) .
$$

Since the target is a finitely generated abelian $p$-group, it suffices to check that

$$
\left(\operatorname{can}-\varphi^{\nabla}\right): \mathrm{F}^{[1,(i-1) n]} \mathrm{N}^{\geqslant i} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} \rightarrow \mathrm{F}^{[1,(i-1) n]} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} /(\mathrm{im}(\nabla), p)
$$

is surjective. Now a map $f: A \rightarrow B$ is surjective if and only if $A / H \rightarrow B / f(H)$ is surjective, for an arbitrary subgroup $H \subseteq A$.

Applying this to the subgroup $\mathrm{F}^{\left[\left\lceil\frac{(i-1) n}{p}\right\rceil+1,(i-1) n\right]} \mathrm{N} \geqslant i \widehat{\Delta}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\}$, we are thus reduced to checking that

$$
\begin{equation*}
\operatorname{can}-\varphi^{\nabla}: \mathrm{F}^{\left[1,\left\lceil\frac{(i-1) n}{p}\right\rceil\right]} \mathrm{N}^{\geqslant} \widehat{\Delta}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} \rightarrow \frac{\mathrm{F}^{[1,(i-1) n]} \widehat{\widehat{\Delta}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\}}{\left(\operatorname{im}(\nabla), p,\left(\operatorname{can}-\varphi^{\nabla}\right) \mathrm{F}^{\left[\left\lceil\frac{(i-1) n}{p}\right\rceil+1,(i-1) n\right]}\right)} \tag{17}
\end{equation*}
$$

is surjective. By assumption,

$$
i-1 \geqslant \frac{p}{p-1}\left(p[j]_{p}-p^{j} j+p^{j} \frac{n}{e}\right)
$$

so

$$
\begin{aligned}
e\left(i-1-\left\lfloor\frac{\left\lceil\frac{(i-1) n}{p}\right\rceil-1}{n}\right\rfloor\right) & \geqslant e\left(i-1-\frac{\left\lceil\frac{(i-1) n}{p}\right\rceil-1}{n}\right) \\
& \geqslant e\left(i-1-\frac{(i-1) n}{p n}\right) \\
& \geqslant e \cdot \frac{p-1}{p} \cdot(i-1) \\
& \geqslant p[j]_{p} e-p^{j}(j e-n) .
\end{aligned}
$$

Thus, Lemma 5.16 applies to show that the can part of (17) is divisible by $p$, thus zero. We are reduced to showing that the $\varphi^{\nabla}$ part of the map (17) is surjective. We claim this holds even when quotienting the target by less, i.e., that the map

$$
\varphi^{\nabla}: \mathrm{F}^{\left[1,\left\lceil\frac{(i-1) n}{p}\right\rceil\right]} \mathrm{N}^{\geqslant i} \widehat{\Delta}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} \rightarrow \mathrm{F}^{[1,(i-1) n]} \widehat{\Delta}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} / \operatorname{im}(\nabla)
$$

is surjective. This follows directly from the form of the prismatic Cartier isomorphism presented in Lemma 5.15.

## 6 Nilpotence of $v_{1}$

It has recently been proven in $[7,31]$ that $L_{T(1)} \mathrm{K}\left(\mathbf{Z} / p^{n}\right) \simeq 0$ for all $n \geqslant 1$, where $L_{T(1)}$ denotes the Bousfield localization at the $T(1)$-equivalence. Recall that a map of spectra $X \rightarrow Y$ is a $T(1)$-equivalence if $X / p\left[v_{1}^{-1}\right] \rightarrow Y / p\left[v_{1}^{-1}\right]$ is an equivalence, where $v_{1}$ is an element of $\mathbf{S} / p$ which induces an equivalence after tensoring with KU. For $p$ odd, such an element exists in $\pi_{2 p-2}(\mathbf{S} / p)$ and is uniquely determined up to units, while, for $p=2$, only $v_{1}^{4} \in \pi_{8}(\mathbf{S} / 2)$ exists. This story is complicated by the fact that $\mathbf{S} / p$ is not an $A_{\infty}$-ring spectrum, that for $p=3$ multiplication is not associative, and that for $p=2$ there is no multiplication; see [45, App. A].

In $\bmod p$ algebraic $K$-theory, the story is somewhat simpler. For all primes $p$, even and odd, there is a class $v_{1} \in \mathrm{~K}_{2 p-2}\left(\mathbf{Z}_{p}, \mathbf{F}_{p}\right)$, which is the image of $v_{1} \in \pi_{2 p-2}(\mathbf{S} / p)$ when $p$ is odd and whose fourth power is the image of $v_{1}^{4} \in \pi_{8}(\mathbf{S} / 2)$ for $p=2$. In this case, $\mathrm{K}\left(\mathbf{Z}_{p} ; \mathbf{F}_{p}\right) \simeq \mathrm{TC}\left(\mathbf{Z}_{p} ; \mathbf{F}_{p}\right)$ and $v_{1}$ arises from a class

$$
v_{1} \in \mathrm{H}^{0}\left(\mathbf{F}_{p}(p-1)\left(\mathbf{Z}_{p}\right)\right)
$$

in syntomic cohomology for degree reasons (see Remark 2.17). The sheared down associated graded

$$
\bigoplus_{i \geqslant 0} \operatorname{gr}_{\text {mot }}^{i} \mathrm{TC}\left(\mathbf{Z}_{p} ; \mathbf{F}_{p}\right)[-2 i] \simeq \bigoplus_{i \geqslant 0} \mathbf{F}_{p}(i)\left(\mathbf{Z}_{p}\right)
$$

is an $\mathbf{E}_{\infty}$-algebra in graded spectra and thus one can invert $v_{1}$ on $\bigoplus_{i \geqslant 0} \mathbf{F}_{p}(i)\left(\mathbf{Z}_{p}\right)$ to obtain $\bigoplus_{i \in \mathbf{Z}} \mathbf{F}_{p}(i)\left(\mathbf{Z}_{p}\right)\left[v_{1}^{-1}\right]$. Similarly, if $R$ is any quasisyntomic $\mathbf{Z}_{p}$-algebra, the element $v_{1}$ acts on $\bigoplus_{i \in \mathbf{Z}} \mathbf{F}_{p}(i)(R)$ and we can form the localization $\bigoplus_{i \in \mathbf{Z}} \mathbf{F}_{p}(i)(R)\left[v_{1}^{-1}\right]$.
Remark 6.1. We will use that $v_{1} \in \mathrm{~K}_{2 p-2}\left(\mathcal{O}_{K} ; \mathbf{F}_{p}\right)$ is non-zero for every $p$-adic field $K$. This follows from the fact that $v_{1}$ maps to (a unit multiple of) $\beta^{p-1}$ in $\mathrm{K}\left(\bar{K} ; \mathbf{F}_{p}\right) \simeq \mathrm{ku} / p$, where $\beta$ denotes the Bott element.
Proposition 6.2. Let $R=\mathcal{O}_{K} / \varpi^{n}$ where $n \geqslant 2$. Let $v \in \mathrm{~N}^{\geqslant p-1} \widehat{\triangle}_{R / W(k) \llbracket z \rrbracket}^{(1)} / p$ be the element $d^{p}$. For $j=\left\lceil\frac{n}{e}\right\rceil$, we have $v^{[j]_{p}}=0$ in $\mathrm{N} \geqslant[j]_{p}(p-1) \widehat{\mathbb{}}_{R / W(k) \llbracket z \rrbracket}^{(1)} /$ p. If e divides $n$, this is sharp, i.e. $v^{[j]_{p}-1} \neq 0$.

Proof. After trivializing the Breuil-Kisin orientation and using $d \sim z^{e}$, we have

$$
v^{[j]_{p}} \sim z^{[j]_{p} e} d^{(p-1)[j]_{p}}=z^{[j]_{p} e} d^{p^{j}-1}
$$

This is zero $\bmod p$ by Lemma 5.9. If $e$ divides $n$, we have $n-e j=0$, and Lemma 5.7 shows that

$$
z^{[j]_{p} e-1} d^{i} \sim z^{n-1} f_{0}^{p-1} \cdots f_{j-2}^{p-1} d^{i-\left(p^{j-1}-1\right)}
$$

is nonzero $\bmod p$ for any large enough $i$, and so in particular

$$
v^{[j]_{p}-1} \sim z^{\left([j]_{p}-1\right) e} d^{(p-1)\left([j]_{p}-1\right)}
$$

is nonzero $\bmod p$.
Theorem 6.3. The class $v_{1} \in \mathrm{H}^{0}\left(\mathbf{F}_{p}(p-1)\left(\mathbf{Z}_{p}\right)\right)$ acts on $\bigoplus_{i \in \mathbf{Z}} \mathbf{F}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)$ with nilpotency degree at most $[j]_{p}$, where $j=\left\lceil\frac{n}{e}\right\rceil$. If e divides $n$, this is the exact nilpotence degree.

Proof. We first locate $v_{1}$ in the relative-to-absolute descent spectral sequence for the syntomic cohomology of $\mathcal{O}_{K}$, finding that there is an exact sequence

$$
0 \rightarrow \mathrm{H}^{0}\left(\mathbf{F}_{p}(p-1)\left(\mathcal{O}_{K}\right)\right) \rightarrow \mathrm{H}^{0}\left(\mathbf{F}_{p}(p-1)\right)\left(\mathcal{O}_{K} / A^{0}\right) \xrightarrow{d^{0}-d^{1}} \mathrm{H}^{0}\left(\mathbf{F}_{p}(p-1)\right)\left(\mathcal{O}_{K} / A^{1}\right)
$$

In particular, by the coconnectivity of the syntomic complexes involved, $v_{1}$ is non-zero in $\mathrm{H}^{0}\left(\mathbf{F}_{p}(p-\right.$ $\left.1)\left(\mathcal{O}_{K} / A^{0}\right)\right)$. By Proposition 4.24, the relative syntomic complex $\mathbf{Z}_{p}(p-1)\left(\mathcal{O}_{K} / A^{0}\right)$ is equivalent to

$$
\mathrm{fib}\left(W(k) \llbracket z_{0} \rrbracket \cdot d^{p-1} \xrightarrow{f\left(z_{0}\right) \cdot d^{p-1} \mapsto\left(f\left(z_{0}\right) d^{p-1}-\varphi\left(f\left(z_{0}\right)\right)\right)} W(k) \llbracket z_{0} \rrbracket\right),
$$

where $d=E\left(z_{0}\right)$ is the distinguished element of the Breuil-Kisin prism $A^{0}$. Working modulo $p$ we find that the complex $\mathbf{F}_{p}(p-1)\left(\mathcal{O}_{K} / A^{0}\right)$ is given by

$$
\mathrm{fib}\left(k \llbracket z_{0} \rrbracket \cdot z_{0}^{p-1} \xrightarrow{f\left(z_{0}\right) \cdot d^{p-1} \mapsto\left(f\left(z_{0}\right)\left(u z_{0}^{e}\right)^{(p-1)}-\varphi\left(f\left(z_{0}\right)\right)\right)} k \llbracket z_{0} \rrbracket\right),
$$

where $u$ is the coefficient of $z_{0}^{e}$ in $E\left(z_{0}\right)$. As $u^{p-1}=1(\bmod p)$, we can rewrite the map as $f\left(z_{0}\right) \mapsto$ $f\left(z_{0}\right) z_{0}^{e(p-1)}-\varphi\left(f\left(z_{0}\right)\right)$ modulo $p$. The kernel of this map is generated by $z_{0}^{e} \cdot d^{p-1}$, so that $\mathrm{H}^{0}\left(\mathbf{F}_{p}(p-\right.$ $\left.1)\left(\mathcal{O}_{K} / A^{0}\right)\right)$ is a 1-dimensional $\mathbf{F}_{p}$-vector space. Thus, by counting dimensions and Remark 6.1, it follows that the class $z_{0}^{e} \cdot d^{p-1} \sim d^{p}=v$ survives to give a unit multiple of $v_{1}$ in the absolute $p$-adic syntomic complex $\mathbf{F}_{p}(p-1)\left(\mathcal{O}_{K}\right)$.

To prove that $v_{1}^{[j]_{p}}=0$ in $\mathbf{F}_{p}\left([j]_{p}(p-1)\right)\left(\mathcal{O}_{K} / \varpi^{n}\right)$ it suffices to show that $d^{p[j]_{p}}$ maps to zero in $\mathbf{F}_{p}\left([j]_{p}(p-\right.$ $1))\left(\left(\mathcal{O}_{K} / \varpi^{n}\right) / A^{0}\right)$. This is the content of Proposition 6.2. The claim about the exact nilpotence degree follows from the same proposition.

We recover the result of $[7,31]$.
Corollary 6.4. For any $n \geqslant 1$ and any prime number $p$,

$$
L_{T(1)} \mathrm{K}\left(\mathbf{Z} / p^{n}\right) \simeq 0
$$

where $T(1)$ denotes the height 1 telescopic localization at the prime $p$.
Proof. We have $L_{T(1)} \mathrm{K}\left(\mathbf{Z} / p^{n}\right) \simeq L_{T(1)} \mathrm{K}\left(\mathbf{Z} / p^{n} ; \mathbf{Z}_{p}\right) \simeq L_{T(1)} \mathrm{TC}\left(\mathbf{Z} / p^{n} ; \mathbf{Z}_{p}\right)$. It is enough to show that $\mathrm{TC}\left(\mathbf{Z} / p^{n} ; \mathbf{F}_{p}\right)\left[v_{1}^{-1}\right]$ vanishes. This follows from Theorem 6.3 and the fact that the motivic filtration induces a finite filtration on each $\pi_{r} \mathrm{TC}\left(\mathbf{Z} / p^{n} ; \mathbf{F}_{p}\right)$ by Corollary 2.16.

Corollary 6.5. Suppose that $p \geqslant 5$ is a prime and that $j=\left\lceil\frac{n}{e}\right\rceil$. Then, for any $n \geqslant 1$, the action of $v_{1}^{2[j]_{p}}$ on $\mathrm{K}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{F}_{p}\right)$ is homotopic to 0 .
Proof. We use that for $p \geqslant 5, \mathrm{~K}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{F}_{p}\right)$ is a homotopy associative ring spectrum. This reduces the corollary to checking that $v_{1}^{2[j]_{p}}=0$ in $\mathrm{K}_{*}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{F}_{p}\right)$. However, $v_{1}^{[j]_{p}}=0$ in

$$
\mathrm{H}^{0}\left(\mathbf{F}_{p}\left([j]_{p}(p-1)\right)\left(\mathcal{O}_{K} / \varpi^{n}\right)\right)
$$

the motivic associated graded, so it lifts to some element, say $\left.x \in \mathrm{H}^{2}\left(\mathbf{F}_{p}\left([j]_{p}(p-1)+1\right)\right)\left(\mathcal{O}_{K} / \varpi^{n}\right)\right)$. But, now, $v_{1}^{[j]_{p}} x=0$ in the motivic associated graded, and thus $v_{1}^{2[j]_{p}}=0$ in $\mathrm{K}_{*}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{F}_{p}\right)$, as claimed.

## 7 An algorithm for syntomic cohomology

Section 7.1 describes our algorithm as we implemented it. Section 7.2 contains an analysis of the $p$-adic precision required in order to guarantee correct results.

### 7.1 The algorithm as implemented

In this subsection, we give the algorithm as implemented in [5] for the computation of the K-groups of $R=\mathcal{O}_{K} / \varpi^{n}$.

Input: integers $q=p^{f}, i, n$ for $f, i, n \geqslant 1$ and an Eisenstein polynomial $E(z) \in W\left(\mathbf{F}_{q}\right)[z]$, assumed to be normalized so that $E(0)=p$ and specified up to the working $p$-adic precision specified in Step 1 below.

Output: $p$-adic matrices $\operatorname{syn}^{0}$ and $\operatorname{syn}^{1}$ defining a complex

$$
\cdots \rightarrow 0 \rightarrow \mathbf{Z}_{p}^{f(i n-1)} \xrightarrow{\operatorname{syn}^{0}} \mathbf{Z}_{p}^{2 f(i n-1)} \xrightarrow{\operatorname{syn}^{1}} \mathbf{Z}_{p}^{f(i n-1)} \rightarrow 0 \rightarrow \cdots
$$

quasi-isomorphic to $\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)$. The cohomology of this matrix can be computed using Smith normal form and gives the cohomology of $\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)$ and hence the structure of $\mathrm{K}_{2 i-2}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right)$ and $\mathrm{K}_{2 i-1}\left(\mathcal{O}_{K} / \varpi^{n} ; \mathbf{Z}_{p}\right)$.

Strategy: we will compute the commutative square

Each of the vertices in this square is a free $W\left(\mathbf{F}_{q}\right)$-module of rank $(i n-1)$. The maps in the diagram are not $W\left(\mathbf{F}_{q}\right)$-linear thanks to Frobenius, but they are of course $\mathbf{Z}_{p}$-linear, so we use $W\left(\mathbf{F}_{q}\right) \cong \mathbf{Z}_{p}^{f}$, to compute matrix representatives for this square in $\mathbf{Z}_{p}$-modules. For the computation of $\nabla$, we will also work in $\widehat{\mathbb{}}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}\{i\}$ and $\widehat{\triangle}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}\{i\}$.

Step 1: find the working $p$-adic precision. Lemma 7.2 shows that $\operatorname{syn}^{0}$ and $\operatorname{syn}^{1}$ should be computed up to $p$-adic precision

$$
\sum_{j=1}^{i n-1} \epsilon(i, j)+v_{p}\{j, n\}
$$

where $\epsilon(i, j)=1$ if $n \mid j$ and 0 otherwise in the given range and $\{j, n\}=n$ if $n \mid j$ and $j$ otherwise (compare Proposition 2.18). This is the target p-adic precision. (It is also possible to work with a smaller target precision, at the cost of potentially having to restart the computation with a larger target precision, see Remark 7.3.) Several steps in the algorithm below result in a cumulative precision loss of at most

$$
\left\lfloor\log _{p}(i n-1)\right\rfloor+\sum_{s=p}^{i-1} n v_{p}(s!)+n\binom{i}{2}+\sum_{j=1}^{i n-1} \epsilon(i, j)+v_{p}\{j, n\}
$$

Thus, all computations in the algorithm below should be made starting at a $p$-adic precision of

$$
2\left(\sum_{j=1}^{i n-1} \epsilon(i, j)+v_{p}\{j, n\}\right)+\left\lfloor\log _{p}(i n-1)\right\rfloor+\sum_{s=p}^{i-1} n v_{p}(s!)+n\binom{i}{2}
$$

the working p-adic precision, although we warn the reader that the effective precision drops in several of the steps below.

Step 2: initialize linear bases. Choose a basis $1, x, x^{2}, \cdots, x^{f-1}$ for $\mathbf{F}_{q}$ over $\mathbf{F}_{p}$ and lift this to a basis for $W\left(\mathbf{F}_{q}\right)$ over $\mathbf{Z}_{p}$. Assume that $x$ satisfies a fixed degree $f$ monic polynomial $h(x)=0$.

A $W\left(\mathbf{F}_{q}\right)$-basis for $\mathrm{F}^{[1, i n-1]} \widehat{\mathbb{}}_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}$ is given by monomials $z_{0}^{k} \prod f_{u}^{e_{u}}$ for $0 \leqslant k<n$ and $1 \leqslant$ $k+\sum n p^{u} e_{u} \leqslant i n-1$ with $e_{u}<p$. A $W\left(\mathbf{F}_{q}\right)$-basis for $\mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\triangle}_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}$ is given by elements of the form $\widetilde{d}^{i}-\sum p^{u} e_{u} z_{0}^{k} \prod f_{u}^{e_{u}}$ with $0 \leqslant k<n, 1 \leqslant k+\sum n p^{u} e_{u} \leqslant i n-1$, and $e_{u}<p$. Bases of $\mathrm{F}^{[1, i n-1]} \widehat{\triangle}_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}\{i\}$ and $\mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\triangle}_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}\{i\}$ are obtained symbolically by multiplying with $w\left(s^{i}\right)$, where $s$ is our preferred filtered crystalline Breuil-Kisin orientation. As $\mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant \star \widehat{\mathbb{\Delta}}_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\}=$ $\mathrm{F}^{[0, i n-2]} \mathrm{N} \geqslant \star-1 \widehat{\triangle}_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}\{i-1\}$, bases for the $\nabla$-terms are described analogously, with certain indexing shifts. This determines $W\left(\mathbf{F}_{q}\right)$-bases on all the terms in the diagram (18). Finally, $\mathbf{Z}_{p}$-bases are given by $x^{d} z_{0}^{k} \prod f_{u}^{e_{u}} w\left(s^{i}\right)$ for $0 \leqslant d<f, 0 \leqslant k<n, 1 \leqslant k+\sum n p^{u} e_{u} \leqslant i n-1$, and $e_{u}<p$ on the lower left term, and analogously for the others, where we present $W\left(\mathbf{F}_{q}\right)=\mathbf{Z}_{p}[x] / \widetilde{h}(x)$ where $h$ is an arbitrary $\mathbf{Z}_{p}$-lift of the minimal polynomial $h(x)$ used to present $\mathbf{F}_{q}$. Let $M_{f}$ be the largest $u$ such that $f_{u}$ appears $\left(M_{f}=\left\lfloor\log _{p}(i-1)\right\rfloor\right.$ if $i>1$ and 0 otherwise).

For $\mathrm{F}^{[1, i n-1]} \widehat{\triangle}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}$ we have a $W\left(\mathbf{F}_{q}\right)$-linear basis $z_{0}, \ldots, z_{0}^{i n-1}$. For $\mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\Delta}_{\widehat{\mathcal{O}}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}$ a

basis $z_{0}^{k} \prod g_{u}^{e_{u}}$ for $1 \leqslant k+p^{u} e_{u} \leqslant i n-1$ and $e_{u}<p$. For $\mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\Delta}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}$, a $W\left(\mathbf{F}_{q}\right)$-linear basis is given by monomials $\widetilde{d^{i}-\sum p^{u} e_{u}} z_{0}^{k} \prod g_{u}^{e_{u}}$ with $1 \leqslant k+\sum p^{u} e_{u} \leqslant i n-1$, and $e_{u}<p$. The Breuil-Kisin twists obtain analogous bases by multiplying with $w\left(s^{i}\right)$ or shifting, respectively. Let $M_{g}$ be the largest $u$ such that $g_{u} \operatorname{appears}\left(M_{f}=\left\lfloor\log _{p}(i n-1)\right\rfloor\right)$.

Step 3: compute relations and structure of the prismatic envelopes. For $\widehat{\triangle}_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}$, find elements $\lambda_{u} \in W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket$ as in Lemma 3.24 and create a lookup table of relations for $f_{u}^{p}$ in the prismatic envelope in terms of those, noting that here the terms $R_{u}^{\prime}$ are all zero (Remark 3.29). We compute the $\delta$ operation on $W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket$ by $\delta(x)=\frac{\varphi(x)-x^{p}}{p}$, so each step of the recursion for $\lambda_{u}$ causes a $p$-adic precision loss by 1 digit. Also create a lookup table for the values of $\varphi_{p^{u}}\left(f_{u}\right)$ following Lemma 3.26.

For the structure of $\widehat{\mathbb{}}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}$, use Construction 3.28 to compute elements $R_{u}^{\prime}$ and a $\delta$-ring structure on $W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket\left[g_{u} \mid 0 \leqslant u \leqslant M_{g}\right]$, using the additional trick that we may rewrite

$$
R_{0}^{\prime}=\frac{\delta\left(z_{1}-z_{0}\right)}{\delta(d)}=\frac{1}{\delta(d)} \sum_{1 \leqslant j \leqslant p-1} \frac{1}{p}\binom{p}{j} g_{0}^{j}
$$

and so may work in $W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket\left[g_{u} \mid 0 \leqslant u \leqslant M_{g}\right]$ instead of the bigger $W\left(\mathbf{F}_{q}\right) \llbracket z_{0}, z_{1} \rrbracket\left[g_{u} \mid 0 \leqslant u \leqslant M_{g}\right]$. Following Lemma 3.24, compute a lookup table of relations for $g_{u}^{p}$ in terms of those. The $\delta$-ring structure from Construction 3.28 is stored in terms of the Frobenius lift

$$
\varphi\left(g_{u}\right)=\varphi(d)^{p^{u}}\left(\lambda_{u} g_{u+1, v}+R_{u}^{\prime}\right)
$$

instead of directly storing the values of $\delta\left(g_{u}\right)$, so each of the applications of $\delta$ in the recursion for $R_{u}^{\prime}$ causes a $p$-adic precision loss by 1 digit, which is the same as for $\lambda_{u}$. Also create a lookup table for the values of $\varphi_{p^{u}}\left(g_{u}\right)$ in following Lemma 3.26.

Subalgorithm: reduce. At various points below, we have to rewrite a general element of one of $\widehat{\mathbb{}}_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}$ or $\widehat{\Delta}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}$ in terms of the chosen linear bases above; we do so using the relations introduced in Step 3. The rewriting process is $W\left(\mathbf{F}_{q}\right)$-linear and we use the relations $z_{0}^{n}=f_{0}$ and the lookup table for $f_{u}^{p}$ from Step 3 in the first case, and $z_{1}=z_{0}+g_{0}$ and the lookup table for $g_{u}^{p}$ from Step 3 in the second case. An application of the reduce subalgorithm means in this context to replace a given polynomial in $z_{0}$ and the $f_{u}$ (or $z_{0}, z_{1}$ and $g_{u}$ ) by an equal term in prismatic cohomology which is expressed as a sum of terms in the $W\left(\mathbf{F}_{q}\right)$-linear basis introduced in Step 2. In practice, we perform this reduction by simultaneously imposing all relations above as well as all of the relations in the lookup table for the $p$ th powers and repeating this process until no further changes occur in $\mathrm{F}^{[1, i n-1]}$. This process converges in F and hence terminates in finite time in $\mathrm{F}^{[1, i n-1]}$. (It is possible to recursively reduce the expressions in the lookup table for the $f_{u}^{p}$ and $g_{u}^{p}$ relations, which seems to improve runtimes in the case of the $f_{u}^{p}$, and worsen runtimes in the case of the $g_{u}^{p}$.)

Step 4: compute the change-of-orientation unit $w(v)$. The map $\nabla$ in Breuil-Kisin weight $i$ involves the unit $w(v)$ from Lemma 4.15. In $\triangle_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket \text {, we have }}$

$$
u=\frac{E\left(z_{1}\right)}{E\left(z_{0}\right)}=1+\frac{E\left(z_{1}\right)-E\left(z_{0}\right)}{z_{1}-z_{0}} b
$$

and thus in $\widehat{\triangle}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0}, z_{1} \rrbracket}^{(1)}$,

$$
w(u)=1+\varphi\left(\frac{E\left(z_{1}\right)-E\left(z_{0}\right)}{z_{1}-z_{0}}\right) \varphi_{1}\left(g_{0}\right)
$$

Using the value of $\varphi_{1}\left(g_{0}\right)$ described in Step 3 , we may compute the value

$$
w(v)=\prod_{r \geqslant 0} \varphi^{r}(w(u))
$$

as the fixed point of the recursion $x=w(u) \cdot \varphi(x)$ in $\mathrm{F}^{[1, i n-1]} \widehat{\triangle}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right)}^{(1)} \llbracket z_{0}, z_{1} \rrbracket$, by iterating (and reducing) until the value remains unchanged, starting with $x=w(u)$. This converges rapidly in the F-filtration and takes around $\left\lfloor\log _{p}(i n-1)\right\rfloor$ number of steps.

Step 5: compute $\nabla: \mathrm{F}^{[1, i n-1]} \widehat{\mathbb{}}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \mathrm{F}^{[1, i n-1]} \widehat{\mathbb{}}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\}$. A basis for $\widehat{\mathbb{\Delta}}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}\{i\}$ is given by $z_{0}^{k} w\left(s^{i}\right)$ for $1 \leqslant k \leqslant i n-1$ and $\nabla\left(z_{0}^{k} w\left(s^{i}\right)\right)$ can be computed as $\left(w\left(s^{i-1}\right)\right.$ times ) the coefficient of $g_{0}$ with respect to the $W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket$-basis $\prod g_{u}^{e_{u}}$ in

$$
w\left(v^{i}\right)\left(z_{0}+g_{0}\right)^{k}-z_{0}^{k}
$$

after reducing. Compute this using the value of $w(v)$ from Step 4.

Step 6: compute the reduction maps $\widehat{\Delta}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \widehat{\mathbb{\Delta}}_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}\{i\}$. Reduce $z_{0}^{k}$ for $1 \leqslant k \leqslant$ in -1 with respect to the relations in $\widehat{\triangle}_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}$ and express as a linear combination of the basis elements $z_{0}^{k} \prod f_{u}^{e_{u}}$ to obtain a matrix red for the map

$$
\widehat{\mathbb{\triangle}}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \widehat{\mathbb{U}}_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}\{i\}
$$

induced by $\mathcal{O}_{K} \rightarrow \mathcal{O}_{K} / \varpi^{n}=R$. Analogously (taking the indexing shift into account), compute a matrix $\operatorname{red}^{\nabla}$ for

$$
\widehat{\triangle}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} \rightarrow \widehat{\Delta}_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} .
$$

Step 7: compute $\nabla: \mathrm{F}^{[1, i n-1]} \widehat{\mathbb{}}_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow \mathrm{F}^{[1, i n-1]} \widehat{\mathbb{}}_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\}$. The map $\nabla$ is natural in $R$, so we may reduce to the $\mathcal{O}_{K}$ case via the commutative diagram

The vertical maps were computed in Step 6 and the upper horizontal map in Step 5. Using that the vertical maps are rational isomorphisms (Lemma 4.64) and that all terms are free $\mathbf{Z}_{p}$ modules, compute the top map as $\left(\text { red }^{\nabla}\right)^{-1} \circ \nabla \circ$ red.

The precision loss is bounded by the $p$-valuation of the determinant of red ${ }^{\nabla}$.

Step 8: compute $\nabla$ on the Nygaard filtration. Use $\nabla$ and the can maps to compute the unique map $\mathrm{N}^{\geqslant i} \nabla$ making the diagram below commute:

Specifically, the can maps are rational isomorphisms by Lemma 4.63, so the top map can be computed as $\operatorname{can}^{-1} \circ \nabla \circ$ can. The resulting matrix has integral entries, but some $p$-adic precision has been lost, bounded by the valuation of the determinant of can.

Step 9：compute can－$\varphi$ ．Compute a matrix for can by reducing each of the basis elements $\widetilde{d^{i}-\sum p^{u} e_{u}} z_{0}^{k} \prod f_{u}^{e_{u}}$ in $\widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}$（replacing $\widetilde{d}$ to $\left.E\left(z_{0}\right)\right)$ ．Compute a matrix for $\varphi$ by reducing

$$
\varphi_{i}\left(\widetilde{d^{i}-\sum p^{u} e_{u}} z_{0}^{k} \prod f_{u}^{e_{u}}\right)=z_{0}^{p k} \prod \varphi_{p^{u}}\left(f_{u}\right)^{e_{u}}
$$

using the values for $\varphi_{p^{u}}\left(f_{u}\right)$ computed in Step 3．Obtain a matrix for

$$
\operatorname{can}-\varphi: \mathrm{F}^{[1, i n-1]} \mathrm{N}^{\geqslant} \widehat{\widehat{\Delta}}_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)} \rightarrow \mathrm{F}^{[1, i n-1]} \widehat{凶}_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}
$$

as the difference．

Step 10：compute can $-\varphi^{\nabla}$ ．Using that $N^{\geqslant i} \nabla$ is a rational isomorphism，compute the unique map can $-\varphi^{\nabla}$ such that

$$
\begin{aligned}
& \mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant i \triangle_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \xrightarrow{\mathrm{N}^{\geqslant i} \nabla} \mathrm{~F}^{[1, i n-1]} \mathrm{N} \geqslant i \triangle_{R / W\left(\mathbf{F}_{q}\right) \llbracket z \rrbracket}^{(1), \nabla}\{i\} \\
& \downarrow \operatorname{can}-\varphi \quad \downarrow \operatorname{can}-\varphi^{\nabla} \\
& \mathrm{F}^{[1, i n-1]} \triangle_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \xrightarrow{\nabla} \mathrm{F}^{[1, i n-1]} \triangle_{R / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\}
\end{aligned}
$$

commutes，as $\nabla \circ(\operatorname{can}-\varphi) \circ\left(\mathrm{N}^{\geqslant i} \nabla\right)^{-1}$ ．There is a precision loss bounded by the valuation of the determinant of $\mathrm{N}^{\geqslant i} \nabla$ ．

Return：$\quad \operatorname{syn}^{0}=\binom{\operatorname{can}-\varphi}{\mathrm{N} \geqslant i}$ and $\operatorname{syn}^{1}=\left(\begin{array}{ll}\nabla, & -\operatorname{can}+\varphi^{\nabla}\end{array}\right)$ at the target $p$－adic precision．

## 7．2 The $p$－adic precision

In order to produce correct results，we give an a priori way of specifying the $p$－adic precision for the algorithm by tracking bounds on the precision loss of the reductions explained in Remark 4．67．

## 7．2．1 The target $p$－adic precision

Let $R=\mathcal{O}_{K} / \varpi^{n}$ ．We have found that $\mathbf{Z}_{p}(i)(R) \simeq \mathrm{F}^{[1, i n-1]} \mathbf{Z}_{p}(i)(R)$ ，which is the total complex of

$$
\begin{aligned}
& \mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \xrightarrow{\mathrm{N} \geqslant i} \mathrm{~N}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\triangle}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} \\
& \downarrow \operatorname{can}-\varphi \quad \downarrow \operatorname{can}-\varphi^{\nabla} \\
& \mathrm{F}^{[1, i n-1]} \widehat{\mathbb{}}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \xrightarrow{\square} \mathrm{F}^{[1, i n-1]} \widehat{凶}_{R / W(k) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} .
\end{aligned}
$$

By Lemma 4.65 （or by crystalline degeneration and［42］），the horizontal maps are injective and their cokernels have orders

$$
\prod_{j=1}^{i n-1} q^{\epsilon(i, j)} q^{v_{p}\{j, n\}} \text { and } \prod_{j=1}^{i n-1} q^{v_{p}\{j, n\}} .
$$

The exponents of these groups are bounded above by the same expressions with $p$ replacing $q$ ．
We will use the following lemma throughout our analysis of $p$－adic precision．
Lemma 7．1．Let $C^{\bullet}$ be a cochain complex of finitely generated free $\mathbf{Z}_{p}$－modules with differentials $d^{s}: C^{s} \rightarrow$ $C^{s+1}$ ．If the cohomology of $C^{\bullet}$ is annihilated by $p^{N}$ ，then the cohomology groups can be computed from knowledge of the differentials up to precision $p^{N+1}$（i．e．，their reductions modulo $p^{N+1}$ ）．If additionally the ranks of each differential is known（for example if $C^{\bullet}$ is bounded），then the cohomology groups can be computed from knowledge of the differentials up to precision $p^{N}$ ．

Proof. The cohomology of $C^{\bullet}$ is in particular torsion. This means that each cohomology group $\mathrm{H}^{s}\left(C^{\bullet}\right)$ can be computed by finding the elementary divisors of $d^{s-1}: C^{s-1} \rightarrow C^{s}$. Indeed, the Smith normal form of $d^{s-1}$ is a diagonal matrix with diagonal entries $\left[1, \ldots, 1, p^{a_{1}}, \ldots, p^{a_{M}}, 0, \ldots, 0\right]$ (up to units). The cohomology in this case is $\bigoplus_{j=1}^{M} \mathbf{Z} / p^{a_{j}}$. By hypothesis, each $a_{j} \leqslant N$. Thus, the diagonal matrix can be computed by computing the Smith normal form in $\mathbf{Z} / p^{N+1}$. 4

For the second statement, note that if we compute the elementary divisors in $\mathbf{Z} / p^{N}$, then some elementary divisors in $\left[1, \ldots, 1, p^{a_{1}}, \ldots, p^{a_{M}}, 0 \ldots, 0\right]$ might be indistinguishable from zero, namely those where $a_{j}=N$. However, if we already know the correct number of zeros in the list of elementary divisors, we can still find the number of elementary divisors with $a_{j}=N$ by taking the difference from the number produced by running the Smith normal form algorithm modulo $p^{N}$ and the given number.

Lemma 7.2 (Target precision). If the matrices $\operatorname{syn}^{0}, \operatorname{syn}^{1}$ in the cochain complex $\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)^{\bullet}$ are computed to p-adic precision

$$
\sum_{j=1}^{i n-1} \epsilon(i, j)+v_{p}\{j, n\}
$$

then the cohomology can be computed by the procedure described above.
Proof. As discussed above, the $p$-exponents of the $\mathrm{F}^{[1, i n-1]} \mathrm{N} \geqslant i \widehat{\triangle}_{R}\{i\}$ and $\mathrm{F}^{[1, i n-1]} \widehat{\Delta}_{R}\{i\}$ terms are bounded by $\sum \epsilon(i, j)+v_{p}\{j, n\}$. Moreover, the ranks of $d^{0}$ and $d^{1}$ are both $f(i n-1)$. So, both parts of Lemma 7.1 apply.

Remark 7.3. Lemma 7.1 guarantees that if a $p$-adic cochain complex is known up to precision $p^{N}$, then as long as the cohomology computed using any given representatives of the maps happens be torsion with $p$-exponent strictly smaller than $N$, then the cohomology computation is correct. This means that instead of running the algorithm with the target precision derived from an a priori upper bound for the $p$-exponent as in Lemma 7.2, we may instead run it with an arbitrary target precision. As long as the computed cohomology groups have strictly smaller exponent than this target precision, they are correct, otherwise, we have to restart at a higher precision. In practice, certain specific steps in the algorithm in this approach might result in division-by-zero errors, which would also have to be caught.

It follows syntomic square should be computed to $p$-adic precision

$$
\sum_{j=1}^{i n-1} \epsilon(i, j)+v_{p}\{j, n\}
$$

which is bounded above for example by $i(n-1)+v_{p}((i n-1)!)$, but is typically smaller, especially as $i$ grows with respect to $n$.

Lemma 7.4 (Target precision in the even range). If the matrix $\operatorname{syn}^{0}$ in the cochain complex $\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right) \bullet$ is computed to p-adic precision $\left\lfloor\frac{f i(n-1)}{2}\right\rfloor$ and $\mathrm{H}^{2}\left(\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)^{\bullet}\right)=0$, then $\mathrm{H}^{1}\left(\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right)^{\bullet}\right)$ is computable.

Proof. Under the vanishing hypothesis, the order of $\mathrm{H}^{1}\left(\mathbf{Z}_{p}(i)\left(\mathcal{O}_{K} / \varpi^{n}\right) \bullet\right)$ is $q^{i(n-1)}$ by Proposition 2.18. The elementary divisors of $\operatorname{syn}^{0}$ are $\alpha_{1}, \ldots, \alpha_{f(i n-1)}, 0, \ldots, 0$, for some $p$-powers $\alpha_{j}$, where there are $f(i n-1)$ copies of zero. Since $\prod_{j=1}^{f(i n-1)} \alpha_{j}=q^{i(n-1)}=p^{f i(n-1)}$, it is enough to compute all but the last non-zero elementary divisor. Let $\nu_{j}=v_{p}\left(\alpha_{j}\right)$. Thus, $0 \leqslant \nu_{1} \leqslant \cdots \leqslant \nu_{f(i n-1)-1} \leqslant \nu_{f(i n-1)}$ is an increasing sequence of integers whose sum is $f i(n-1)$. The worst case is when $\nu_{f(i n-1)-1}$ is as large as possible, which is when $\nu_{f(i n-1)-1}=\left\lfloor\frac{f i(n-1)}{2}\right\rfloor$ (and $\nu_{f(i n-1)}=\left\lceil\frac{f i(n-1)}{2}\right\rceil$ ). These can be computed to the necessary precision by using the Smith normal form as in the proof of Lemma 7.1.

[^3]
### 7.2.2 Precision loss from $\delta$

Applying $\delta$ results in a loss of a single digit of $p$-adic precision, as we compute the $\delta$-structure from $\delta(x)=$ $\frac{\varphi(x)-x^{p}}{p}$. Thus, each time $\delta$ is applied in the construction of the prismatic envelopes, we lose a digit of precision. This causes $\lambda_{u}$ in Step 3 above to be known with a precision $u+1$ less than the initial precision. Similarly, it causes the $R_{u}^{\prime}$ appearing in the relations for $g_{u}^{p}$ to be known to precision $u+2$ less than the initial precision.

Lemma 7.5 (Precision loss from $\delta$ ). (a) Working in p-adic power series with p-adic precision $N$, the units $\lambda_{u}$ are computed with p-adic precision $N-u-1$, and the $R_{u}^{\prime}$ are computable with p-adic precision $N-u-2$.
(b) The largest index $u$ appearing in the required relations and values of $\varphi_{p^{u}}\left(f_{u}\right)$ and $\varphi\left(f_{u}\right)$ is $u=M_{f}-1$. The largest index $u$ appearing in the required relations and values of $\varphi_{p^{u}}\left(g_{u}\right)$ and $\varphi\left(g_{u}\right)$ is $u=M_{g}-1$.
(c) All necessary data in Step 3 is computed to $p$-adic precision $N-\left\lfloor\log _{p}(\right.$ in -1$\left.)\right\rfloor-1=N-M_{g}-1$.

Proof. Part (a) follows from the inductive definition of the $R_{u}^{\prime}$ from Construction 3.28. The others are clear from the fact that in $\mathrm{F}^{[1, i n-1]}$ only $f_{0}, \ldots, f_{M_{f}}$ and $g_{0}, \ldots, g_{M_{g}}$ are involved, and $f_{M_{f}}^{p}$ and $\varphi_{p^{M_{f}}}\left(f_{M_{f}}\right)$ etc. vanish for weight reasons already.

### 7.2.3 Precision loss from passage from $\mathcal{O}_{K}$ to $\mathcal{O}_{K} / \varpi^{n}$

The map $\mathrm{F}^{[1, i n-1]} \widehat{\triangle}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \xrightarrow{\nabla} \mathrm{F}^{[1, i n-1]} \widehat{\triangle}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\}$ can be computed exactly (i.e., without further loss of precision). It is also straightforward to compute the reduction maps $\mathrm{F}^{[1, i n-1]} \widehat{\mathbb{}}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}\{i\} \rightarrow$ $\mathrm{F}^{[1, i n-1]} \widehat{\mathbb{}}_{\left(\mathcal{O}_{K} / \varpi^{n}\right) / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1)}\{i\}$ and $\mathrm{F}^{[1, i n-1]} \widehat{\widehat{\Delta}}_{\mathcal{O}_{K} / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1), \nabla}\{i\} \rightarrow \mathrm{F}^{[1, i n-1]} \widehat{\widehat{\Delta}}_{\left(\mathcal{O}_{K} / \varpi^{n}\right) / W\left(\mathbf{F}_{q}\right) \llbracket z_{0} \rrbracket}^{(1),}\{i\}$ without further loss of precision.

Lemma 7.6 (Precision loss from $\nabla$ on $\left.\mathcal{O}_{K} / \varpi^{n}\right)$. Filling in the square

involves a precision loss of at most $\sum_{s=p}^{i-1} n v_{p}(s!)$.
Proof. By Lemma 4.64, the left vertical map red is rationally invertible. Inverting it results in a matrix with entries in $\mathbf{Q}_{p}$. By considering the Smith normal form of red, it is clear that its inverse has $p$-adic valuation bounded below by $-\sigma$, where $\sigma$ is the valuation of the largest elementary divisor of red. This agrees with the exponent of its cokernel. Since the cokernel has order

$$
\prod_{j=1}^{i n-1} q^{v_{p}\left(\left\lfloor\frac{j}{n}\right\rfloor!\right)}
$$

and is a finite $W\left(\mathbf{F}_{q}\right)$-module, its exponent is bounded by

$$
\sum_{j=1}^{i n-1} v_{p}\left(\left\lfloor\frac{j}{n}\right\rfloor!\right)=\sum_{j=p n}^{i n-1} v_{p}\left(\left\lfloor\frac{j}{n}\right\rfloor!\right)=\sum_{s=p}^{i-1} n v_{p}(s!)
$$

Remark 7.7. In particular, there is no precision loss in this step up to weight $i=p$.

### 7.2.4 Precision loss from computing the Nygaard lift of $\nabla$

Lemma 7.8 (Precision loss from $\mathrm{N}^{\geqslant i} \nabla$ ). Filling in the square

involves a precision loss of at most $n\binom{i}{2}$.
Proof. By Lemma 4.63, the right-hand vertical map is rationally invertible and has cokernel of order

$$
\prod_{j=1}^{i n-1} q^{i-1-\left\lfloor\frac{j-1}{n}\right\rfloor}=\prod_{s=0}^{i-2} q^{n(i-1-s)}=q^{n\binom{i}{2}} .
$$

Since it is a $W\left(\mathbf{F}_{q}\right)$-module, its exponent is bounded by $n\binom{i}{2}$, so we conclude as in the previous argument that inverting the right-hand map causes a precision loss of at most $n\binom{i}{2}$.

### 7.2.5 Precision loss from computing can $-\varphi$ on the primitives

Lemma 7.9 (Precision loss from can $-\varphi^{\nabla}$ ). Filling in the square

involves a precision loss of at most $\sum_{j=1}^{i n-1} \epsilon(i, j)+v_{p}\{j, n\}$.
Proof. As in the proof of Lemma 7.6, the $p$-adic valuation of the exponent of the cokernel of the top horizontal map is bounded above by $\sum_{j=1}^{i n-1} \epsilon(i, j)+v_{p}\{j, n\}$ by the analysis in Section 7.2.1.

## A Tables

In this section we include calculations for the $p$-adic K -groups of $\mathbf{Z} / p^{n}$ for some small $p$ and $n$. More extensive calculations for other rings of the form $\mathcal{O}_{K} / \varpi^{n}$ have been made and will be released elsewhere. The labels refer to local fields in the $\operatorname{lmfdb}$ [34]. All calculations were performed on the high-performance cluster QUEST at Northwestern University.

Each entry in the table consists of a list of positive integers or the mark ' $x$ '. In the former case, it is a list of the exponents in the decomposition of a given K -group into cyclic groups. For example, $\mathrm{K}_{15}\left(\mathbf{Z} / 3^{2} ; \mathbf{Z}_{3}\right)$ is given as $1,1,6$, which means the group is isomorphic to $\mathbf{Z} / 3^{1} \oplus \mathbf{Z} / 3^{1} \oplus \mathbf{Z} / 3^{6}$. An empty list implies the group is zero. A mark ' $x$ ' indicates that the calculation did not succeed in the allotted time ( 48 hours per computation) on QUEST.

[^0]:    ${ }^{1}$ Note that $\left\lceil\frac{n}{e}\right\rceil$ is the exponent of the abelian group $\mathcal{O}_{K} / \varpi^{n}$.

[^1]:    ${ }^{2}$ In [30], two of us used a closely related fiber sequence $\operatorname{THH}\left(R ; \mathbf{Z}_{p}\right) \rightarrow \mathrm{THH}\left(R / \mathbf{S}[z] ; \mathbf{Z}_{p}\right) \rightarrow \mathrm{THH}\left(R / \mathbf{S}[z] ; \mathbf{Z}_{p}\right)[2]$ to give a new computation of the homotopy groups of $\operatorname{THH}\left(R ; \mathbf{Z}_{p}\right)$ for $R$ of the form $\mathcal{O}_{K}$ or $\mathcal{O}_{K} / \varpi^{n}$. This is a fiber sequence of spectra and the first map is naturally a map of cyclotomic spectra, but the cofiber term has a complicated cyclotomic structure. It has never been clear how to use this to give a computation, even of $\operatorname{TP}\left(R ; \mathbf{Z}_{p}\right)$, the issue being that the structure of the $S^{1}$-Tate construction of the cofiber remains mysterious. The descent approach below can be viewed either as a way around this or as a way to access this mystery term.

[^2]:    ${ }^{3}$ Recall that $A\{a\}$ is isomorphic to the countably-generated polynomial ring $\left.A\left[a, \delta(a), \delta^{2}(a), \ldots\right]\right)$ and that the $\delta$-ideal $(d a-r)_{\delta}$ is equal to the ideal $\left(d a-r, \delta(d a-r), \delta^{2}(d a-r), \ldots\right)$.

[^3]:    ${ }^{4}$ For the Smith normal form in principal ideal rings (as opposed to domains), see for example [13, Chap. 15].
