SMALL NOISE PERTURBATIONS OF STOCHASTIC ERGODIC CONTROL PROBLEMS

K. SURESH KUMAR AND DESAI, VIKRANT

ABSTRACT. Using small noise limit approach, we study degenerate stochastic ergodic control problems and as a byproduct obtain error bounds for the ε -optimal controls. We also establish tunneling for a special ergodic control problem and give a representation of the ergodic value using the tunneled Markov chain.

1. INTRODUCTION

We study degenerate stochastic control problems using "small noise" perturbation analysis. i.e., we approach the original as a limit of non-degenerate controlled diffusions given by small noise perturbations. This is in the spirit of a proposal of Kolmogorov as cited in [7] to select a 'physical solution' for an ill-posed problem by looking at the small noise limit of its stochastic perturbation. This is also the philosophy behind the vanishing viscosity method for solving elliptic/parabolic pdes. Since we are concerned with ergodic control problems, the behaviour of the invariant probability measures of the state dynamics enter the picture. Naturally one expects that the asymptotic behaviour of the invariant measure of the small noise perturbation, as perturbation noise approach zero, play a role in the small noise limit of the ergodic control problem. Small noise perturbation of dynamical systems governed by odes and the asymptotics of the invariant probability measures is studied in Chapter 6, [9] when state space is compact and in [2] when state space is \mathbb{R}^d . Small noise limit analysis leads to a selection procedure of invariant measure for the limiting dynamics which may possess multiple invariant probability measures, see [15]. Analogous to the selection procedure for the invariant measures, does small noise perturbation of the ergodic optimal control problem selects in the limit a unique optimal ergodic control problem for the original degenerate controlled state dynamics We get an affirmative answer under suitable conditions. We call this as 'physical' ergodic control problem. The selection is achieved through the selection of an invariant probability measure from the multiple invariant probability measures of the optimal state dynamics and hence our result also can be thought as a controlled version of the selection procedure described in [9]. For a special case, we see a tunneling of the optimal state dynamics and arrive at a representation of the ergodic value through the tunneled Markov chain.

We consider degenerate stochastic control problem with state dynamics governed by the controlled degenerate stochastic differential equation

(1.1) $dX(t) = m(X(t), U(t))dt + \sigma(X(t))dW(t).$

Date: May 2, 2024.

SURESH AND VIKRANT

The functions $m : \mathbb{R}^d \times \mathcal{P}(\mathbb{U}) \to \mathbb{R}^d, \sigma : \mathbb{R}^d \to \mathbb{R}^d \otimes \mathbb{R}^d$ are bounded measurable, with $\mathcal{P}(\mathbb{U})$ denoting the space of probability measures on a compact metric space \mathbb{U} endowed with the Prohorov topology. Note that $\mathcal{P}(\mathbb{U})$ is a compact Polish space¹. $W(\cdot)$ is a *d*-dimensional Wiener process and $U(\cdot)$ is a $\mathcal{P}(\mathbb{U})$ -valued process which is progressively measurable with respect to a right-continuous filtration $\{\mathcal{F}_t\}$ which is complete with respect to the underlying probability measure, and furthermore, is non-anticipative with respect to $W(\cdot)$, i.e., for $t > s \ge 0$, W(t) - W(s) is independent of \mathcal{F}_s . We denote the set of admissible controls by \mathcal{U} .

Furthermore, we assume that m is of the form

(1.2)
$$m(x,U) = \int_{\mathbb{U}} \bar{m}(x,u)U(du), x \in \mathbb{R}^d, U \in \mathcal{P}(\mathbb{U})$$

where $\bar{m} : \mathbb{R}^d \times \mathbb{U} \mapsto \mathbb{R}^d$ is locally bounded and measurable.

The cost criteria is given by

(1.3)
$$\rho(x, U(\cdot)) = \liminf_{t \to \infty} \frac{1}{t} E_x \Big[\int_0^t r(X(s), U(s)) ds \Big], \ U(\cdot) \in \mathcal{U}$$

where the prescribed 'running cost function' $r : \mathbb{R}^d \times \mathcal{P}(\mathbb{U}) \mapsto \mathbb{R}$ is of the form

(1.4)
$$r(x,U) = \int_{\mathbb{U}} \bar{r}(x,u)U(du)$$

and $E_x[\cdot]$ denote the expectation with respect to the law of the process $(X(\cdot), U(\cdot))$ given by (1.1) with initial condition $X(0) = x \in \mathbb{R}^d$. We set $\rho(x, U(\cdot)) = \infty$ if corresponding to $U(\cdot) \in \mathcal{U}$, the stochastic differential equation (in short sde) (1.1) has no solution with initial condition x.

The structural assumptions (1.2), (1.4) on m, r given above is a part of the so called *relaxed control formulation* introduced by L. C. Young [17], which in particular ensures the existence of an optimal control under fairly general conditions.

We say that an admissible control $U(\cdot)$ is a Markov control if $U(t) = u(t, X(t)), t \ge 0$ for some measurable map $u : [0, \infty) \times \mathbb{R}^d \to \mathcal{P}(\mathbb{U})$, where $X(\cdot)$ is a weak solution to (1.1) corresponding to $u(\cdot)$. We denote the set of all Markov controls by \mathcal{U}_M and by an abuse of notation we take

 $\mathcal{U}_M = \{ u : [0, \infty) \times \mathbb{R}^d \to \mathcal{P}(\mathbb{U}) \mid u \text{ is measurable, sde (1.1) has a weak solution corresponding to } u(\cdot) \}.$

When a Markov control $u(\cdot)$ doesn't has an explicit dependence on t, we call it as a stationary Markov control and the set of all stationary Markov controls is denoted by \mathcal{U}_{SM} . Set

$$\hat{\mathcal{U}}_{SM} = \{ u : \mathbb{R}^d \to \mathcal{P}(\mathbb{U}) \mid u \text{ is measurable} \}.$$

We use the following topology on $\hat{\mathcal{U}}_{SM}$ described in [1], p.57. Consider $L^{\infty}(\mathbb{R}^d; \mathcal{M}_s(\mathbb{U}))$ endowed with weak*-topology, where $\mathcal{M}_s(\mathbb{U})$ denote the space of signed Borel measures on \mathbb{U} endowed with weak* topology. Then $\hat{\mathcal{U}}_{SM}$ is a subset of the unit ball in $L^{\infty}(\mathbb{R}^d; \mathcal{M}_s(\mathbb{U}))$ and hence is given the relative topology. Under this weak* topology $\hat{\mathcal{U}}_{SM}$ is compact due to Banach-Algaoglu theorem and is metrizable and the

¹More generally, we shall denote by $\mathcal{P}(\cdots)$ the Polish space of probability measures on the Polish space \cdots with Prohorov topology.

topolgy can be characterized by the following convergence criterion. $u_n \to u$ in $\hat{\mathcal{U}}_{SM}$ if for $f \in L^1(\mathbb{R}^d) \cap L^2(\mathbb{R}^d), g \in C_b(\mathbb{R}^d \times \mathbb{U}),$

(1.5)
$$\lim_{n \to \infty} \int_{\mathbb{R}^d} f(x) \int_{\mathbb{U}} g(x, v) u_n(x) (dv) dx = \int_{\mathbb{R}^d} f(x) \int_{\mathbb{U}} g(x, v) u(x) (dv) dx.$$

For \mathcal{U}_{SM} , we use the relative topology described above. When $\sigma = 0$, we can see that $\hat{\mathcal{U}}_{SM} = \mathcal{U}_{SM}$.

We also use smooth controls defined in the following sense. $u \in \mathcal{U}_{SM}$ is said to be smooth if $x \mapsto \int_{\mathbb{U}} f(v)u(x)(dv)$ is smooth for all $f \in C(\mathbb{U})$. We denote the set of all smooth controls by $\mathcal{U}_{SM}^{smooth}$.

We can view any admissible control $U(\cdot)$ as a \mathcal{U}_D -valued random variable, where $\mathcal{U}_D = \{u : [0, \infty) \to \mathcal{P}(\mathbb{U}) | u \text{ is measurable}\}.$ We then say that $U_n(\cdot) \to U(\cdot)$ in law if the law of $U_n(\cdot)$ converges to the law of $U(\cdot)$ in $\mathcal{P}(\mathcal{U}_D)$. By Prohorov's theorem, $\mathcal{P}(\mathcal{U}_D)$ is a compact Polish space.

We can also view $U(\cdot) \in \mathcal{U}$ as a prescribed control in the sense that, one defines $U(\cdot)$ on a given $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, P, W(\cdot))$. For instance, given a feedback control $u(\cdot)$, if $(X(\cdot), W(\cdot))$ is a weak solution to (1.1) defined on a filtered probability space $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, P)$ and $\{\mathcal{F}_t\}$ - Wiener process $W(\cdot)$, then the process $U(t) = u(t, X_{[0,t]})$, where $X_{[0,t]} = \{X(s)|0 \leq s \leq t\}$ is a prescribed control on $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, P, W(\cdot))$. This way we treat any feedback control as a prescribed control.

Before proceeding further, we briefly list notations used in the article. For the Euclidean space \mathbb{R}^d , $x \in \mathbb{R}^d$, x_i denotes its *i*th component and $\|\cdot\|$ denotes

$$||x|| = \sqrt{x_1^2 + \dots + x_d^2}, \ x \in \mathbb{R}^d,$$

 $x \in \mathbb{R}^d$ is treated as a row vector. For $A \in \mathbb{R}^d \otimes \mathbb{R}^d$, the set of all $d \times d$ real matrices, we use $||A|| = \sqrt{\sum_{i,j=1}^d a_{ij}^2}$, $A = (a_{ij})$, A^T denotes the transpose of A and $I \in \mathbb{R}^d \otimes \mathbb{R}^d$ denotes the identity matrix. $C^k(\mathbb{R}^d)$, k = 0, 1, 2, denote the space of all functions with continuous partial derivatives of order up to k. For a function $f \in C^1(\mathbb{R}^d)$, ∇f denotes the gradient and for a function $f \in C^2(\mathbb{R}^d)$, $\nabla^2 f$ denotes the gradient and for a function $f \in C^2(\mathbb{R}^d)$, $\nabla^2 f$ denotes the Hessian of f and Δf denotes its Laplacian. $C_c^{\infty}(\mathbb{R}^d)$ denote the space of all smooth compactly supported functions defined on \mathbb{R}^d . For the compact metric space \mathbb{U} , $C(\mathbb{U})$ denotes the space of all continuous functions $f : \mathbb{U} \to \mathbb{R}$ with sup norm $||f||_{\infty} = \sup_{u \in \mathbb{U}} |f(u)|$. Also we denote the set of all Lipschitz continuous function on \mathbb{R}^d by $C^{0,1}(\mathbb{R}^d)$. For $f \in C^{0,1}(\mathbb{R}^d)$, we denote its Lipschitz constant by $\operatorname{Lip}(f)$. We also use the Sobolev space $W^{2,p}(\mathbb{R})$, $p \geq 2$, the set of all $f \in L^p(\mathbb{R})$ such that $f' \in L^p(\mathbb{R})$ with the p-Sobolev norm.

We use K > 0 to denote the constant appearing in (A1)(ii). Other constants are denoted by \hat{K}, K_0, K_1, K_2 etc., their values will change from place to place depending on the context.

Controlled diffusion process $\{X(t)|0 \le t < \infty\}$ will also be denoted by X or $X(\cdot)$. We use the following parametric family of infinitesimal generators.

(1.6)
$$\mathcal{L}^{U}f(x) = \frac{1}{2}\operatorname{trace}(a(x)\nabla^{2}f) + \langle m(x,U), \nabla f \rangle,$$
$$\mathcal{L}^{U}_{\varepsilon}f(x) = \frac{1}{2}\operatorname{trace}(a_{\varepsilon}(x)\nabla^{2}f) + \langle m(x,U), \nabla f \rangle.$$

where $a = \sigma \sigma^T, a_{\varepsilon} = \sigma_{\varepsilon} \sigma_{\varepsilon}^T, \sigma_{\varepsilon}$ is a suitable non degenerate perturbation of σ defined in forthcoming sections.

We say that $(X(\cdot), U(\cdot))$ is an admissible pair if $U(\cdot) \in \mathcal{U}$ and $X(\cdot)$ is a weak solution to the sde (1.1) corresponding to $U(\cdot)$.

Definition 1.1. (i) Admissible control $U^*(\cdot)$ is ergodic optimal if

(1.7)
$$\rho(x, U^*(\cdot)) \leq \rho(x, U(\cdot)), \text{ for all } U(\cdot) \in \mathcal{U}, \ x \in \mathbb{R}^d.$$

(ii) Admissible pair $(X^*(\cdot), U^*(\cdot))$ is an ergodic optimal pair if

$$\liminf_{t \to \infty} \frac{1}{t} E\Big[\int_0^t r(X^*(s), U^*(s))ds\Big] \le \liminf_{t \to \infty} \frac{1}{t} E\Big[\int_0^t r(X(s), U(s))ds\Big]$$

for all admissible pair $(X(\cdot), U(\cdot))$ of (1.1).

Let \mathcal{G} denote the set of all ergodic occupation measures of the process (1.1), i.e.

$$\mathcal{G} = \left\{ \pi \in \mathcal{P}(\mathbb{R}^d \times \mathbb{U}) \middle| \iint \mathcal{L}^U f(x, u) \pi(dx du) = 0, \text{ for all } f \in C_c^\infty(\mathbb{R}^d) \right\},\$$

see Chpater 6 of [1] for details. We introduce various notions of values for ergodic optimal control.

$$(\mathfrak{A}^{*}\mathfrak{B}) = \inf_{\pi \in \mathcal{G}} \iint \bar{r}(x, u) \pi(dxdu), \ \rho^{*} = \inf_{(X(\cdot), U(\cdot))} \liminf_{t \to \infty} \frac{1}{t} E \Big[\int_{0}^{t} r(X(s), U(s)) ds \Big]$$

$$\rho_{\mathcal{U}}^{*}(x) = \inf_{U(\cdot) \in \mathcal{U}} \rho(x, U(\cdot)), \ x \in \mathbb{R}^{d}, \ \rho_{\mathcal{U}}^{*} = \inf_{x \in \mathbb{R}^{d}} \rho_{\mathcal{U}}^{*}(x),$$

$$^{*} (x) = \inf_{u \in \mathcal{U}} \rho(x, U(\cdot)), \ x \in \mathbb{R}^{d}, \ \rho_{\mathcal{U}}^{*} = \inf_{x \in \mathbb{R}^{d}} \rho_{\mathcal{U}}^{*}(x),$$

$$\rho_{\mathcal{U}_{SM}}^*(x) = \inf_{U(\cdot)\in\mathcal{U}_{SM}}\rho(x,U(\cdot)), \ x\in\mathbb{R}^d, \ \rho_{\mathcal{U}_{SM}}^* = \inf_{x\in\mathbb{R}^d}\rho_{\mathcal{U}}^*(x),$$

where infimum in the second equality is over all admissible solution pair $(X(\cdot), U(\cdot))$. Clearly $\rho^* \leq \rho^{**} \leq \rho^*_{\mathcal{U}} \leq \rho^*_{\mathcal{U}_{SM}}$. Under (A1) and standard stability assumptions, all the above ergodic optimal values coincide when (1.1) satisfies the non degeneracy condition but that may not be the case with out the non degeneracy condition.

We assume:

- Assumption (A1). The functions $\bar{m} = (\bar{m}_1, \dots, \bar{m}_d)$, \bar{r} are jointly continuous and Lipschitz in the first variable uniformly with respect to the second, σ is Lipschitz continuous and bounded and $\sigma\sigma^T \ge 0$.
 - There exists $K \in \mathbb{R}$ such that

$$\langle \bar{m}(x,u) - \bar{m}(y,u), x - y \rangle + \frac{1}{2} \|\sigma(x) - \sigma(y)\|^2 \leq K \|x - y\|^2, x, y, \in \mathbb{R}^d, u \in \mathbb{U}.$$

Now let us briefly indicate what is known about ergodic control problems when the state dynamics are degenerate, i.e. when the diffusion matrix doesn't satisfies the uniform ellipticity condition. Following general result is known, see [[1], Chapter 7, Theorem 7.2.1, p.254].

Theorem 1.2. Assume (A1) and that the map $(x, U) \mapsto \mathcal{L}^U V(x)$ is inf-compact for some non negative inf-compact $V \in C^2(\mathbb{R}^d)$. Then there exists an optimal ergodic pair $(X(\cdot), U(\cdot))$ such that $X(\cdot)$ is a Markov and $U(\cdot)$ can be taken as a stationary Markov control.

Hence Theorem 1.2 doesn't give an optimal control in the sense of Definition 1.1 (i) but give an existence result in the sense of Definition 1.1 (ii).

Under an additional assumption of asymptotic flatness on the state dynamics, i.e. K < 0 in (A1) (ii), the following is proven in [[1], Chapter 7].

Theorem 1.3. Assume (A1) with K < 0. Then there exists $\pi^* \in \mathcal{G}$ such that $\rho^* = \iint \overline{r}(x, u) \pi^*(dxdu)$ and if $(X^*(\cdot), U^*(\cdot))$ denote a stationary solution pair corresponding to π^* , then given any $x \in \mathbb{R}^d$,

$$\liminf_{t \to \infty} \frac{1}{t} E_x \left[\int_0^t r(X(s), U^*(s)) ds \right] = \rho^*,$$

where $X(\cdot)$ denote the solution to (1.1) corresponding to $U^*(\cdot)$ and initial condition $x \in \mathbb{R}^d$. More over

$$\rho(x, U^*(\cdot)) \le \rho(x, U(\cdot)), \text{ for all } x \in \mathbb{R}^d, U(\cdot) \in \mathcal{U}.$$

Thus, Theorem 1.3 gives the existence of optimal control in the sense of Definition 1.1 (i). But neither the theorem nor the method of proof throw any light on the computation of the optimal control, though they give a characterization of the value ρ^* as a viscosity solution of the corresponding HJB equation in the asymptotic flat case, see Theorem 7.3.10 of [1], p.260.

Our contribution is manyfold. Firstly we observe in Theorem 2.1 that small noise limit of the degenerate ergodic optimal control problem selects the ergodic optimal control problem which seeks minimization over all admissible pairs, i.e., Definition 1.1 (ii). Also Theorem 2.3 and Theorem 2.4 indicate that this need not be a solution for the ergodic control problem in Definition 1.1 (i). i.e., small noise limit need not select in general the ergodic control problem in the sense of Definition 1.1 (i). This parallels the selection of physically relevant invariant probability measure from the set of all invariant measures/equilibrium of a given dynamical system. Hence we can observe that ergodic control problem in the sense of Definition 1.1 (ii) is the relevant problem when the underlying state dynamics seeks 'thermalization'. When the state dynamics of the ergodic control problem is a controlled deterministic gradient flow, we establish a tunneling behavior for the one dimensional ergodic control problem and give a representation of the value ρ^* in terms of the continuous time Markov chain which represents the tunneling of the controlled state dynamics corresponding to the ergodic optimal Markov control.

Secondly, we explore sufficient conditions for the small noise approximation of the ergodic control problem in the sense of Definition 1.1 (i). We show that the small noise approximation of the ergodic control problem converges to ergodic optimal control problem in the sense of Definition 1.1 (i) first in the case when the state dynamics satisfies the asymptotic flaness condition given by (A1) with K < 0. Under a different set of sufficient conditions, i.e. (B) and (D), we show the convergence to the ergodic optimal control problem in the sense of Definition 1.1 (i) among the class of stationay Markov controls.

Thirdly, we obtain error bounds for approximate controls which are ergodic optimal control for the perturbed non degenerate ergodic control problem whose optimal control can be characterized using the minimizing selector of corresponding HJB equation and hence computable, see Theorem 4.6.

The paper is organized as follows. In Section 2, we give a selection theorem for the degenerate ergodic control problems using small noise limit, see Theorem 2.1. In Theorem 2.3, we show that the optimal control corresponding to the value ρ^* is optimal in the sense of Definition 1.1 (i) for the initial values x in the support of the invariant probability measure of the sde (1.1) corresponding to optimal control. This in particular implies that $\rho^* = \rho^*_{\mathcal{U}}$. In Section 3 we address the problem when the state dynamics satisfies certain asymptotic flat condition. In Theorem 3.3, we show that small noise limit of the ergodic control problem is the ergodic control problem in the sense of Definition 1.1 (i) and also gives an error bound for the approximate optimal controls. In Section 4, we consider the degenerate ergodic control problem under more general conditions. Under suitable conditions, in Theorem 4.6, we show that the small noise limit of the ergodic control problem becomes Definition 1.1 (i) among the class of stationay Markov controls. We also show the existence of ε optimal controls over the space of stationary Markov strategies in Theorem 4.7. Also under an additional condition, we obtain error bounds in Theorem 4.9. Note that we were only showing the existence of ε -optimal controls when minimization is over \mathcal{U}_{SM} . So we do not know whether the value $\rho_{\mathcal{U}}^*$ coinsides with the value $\rho_{\mathcal{U}_{SM}}^*$. But we have affirmative answer for a special case in Theorem 4.12. In Section 5, we prove in Theorem 5.10 which gives a characterization of the optimal ergodic value ρ^* in terms of the underlying Markov chain which represents the tunneling of the optimaly controlled state dynamics. In Section 6, we give the proof of a characterization for invariant probability distribution for solutions of sdes which are probably non Feller.

2. Degenerate Ergodic control: General results

In this section, we give a selection theorem for degenerate optimal control problems in the following sense. The small noise perturbation limit of the ergodic control problem pick the ergodic value ρ^* which is the minimum among all ergodic optimal values given in (1.8). Along with (A1), we assume the following stability condition.

Assumption (L). The map $(x, U) \mapsto \mathcal{L}^U \hat{V}(x)$ from $\mathbb{R}^d \times \mathbb{U}$ to \mathbb{R} is inf-compact for some positive inf-compact $\hat{V} \in C^2(\mathbb{R}^d)$, where \mathcal{L}^U is as in (1.6).

Consider the small noise perturbation of the ergodic optimal control problem (1.1);(1.3) with state dynamics

(2.1)
$$dX^{\varepsilon}(t) = m(X^{\varepsilon}(t), U(t))dt + \sigma_{\varepsilon}(X^{\varepsilon}(t))dW(t),$$

and cost criterion

(2.2)
$$\rho_{\varepsilon}(x, U(\cdot)) = \liminf_{t \to \infty} \frac{1}{t} E_x \Big[\int_0^t r(X^{\varepsilon}(s), U(s)) ds \Big], \ U(\cdot) \in \mathcal{U}.$$

where $X^{\varepsilon}(\cdot)$ is a solution to (2.1) satisfying $X^{\varepsilon}(0) = x$ corresponding to the admissible control $U(\cdot)$. The choice of the perturbation σ_{ε} of σ is as follows. For $\varepsilon > 0$, choose $\sigma_{\varepsilon} : \mathbb{R}^d \to \mathbb{R}^d \otimes \mathbb{R}^d$ such that

$$(i) \sigma_{\varepsilon} \sigma_{\varepsilon}^{T} \ge \varepsilon I, \ (ii) \sup_{x \in \mathbb{R}^{d}} \|\sigma_{\varepsilon}(x) - \sigma(x)\| \le \varepsilon |K|, \ (iii) \|\sigma_{\varepsilon}(x) - \sigma_{\varepsilon}(y)\| \le \|K\| \|x - y\|,$$

for some $K \in \mathbb{R}$. The constant K is chosen without any loss of generality as the constant in (A1)(ii). One such choice is given by $\sigma_{\varepsilon}\sigma_{\varepsilon}^{T} = \sigma\sigma^{T} + \varepsilon^{2}I$, i.e., σ_{ε} is a small 'noise' perturbation of σ .

Assumption (H1). For $\pi(dxdu) = u(x)(du)\eta(dx) \in \mathcal{G}$, we assume that $\eta(dx)$ is a limit point of the invariant probability measure $\eta^{\varepsilon}(dx)$ of the process $X^{\varepsilon}(\cdot)$ given by (2.1) corresponding to $u(\cdot)$.

Assumption (H2). For each $u \in \mathcal{U}_{SM}$ and $\delta > 0$, there exist $u_{\delta} \in \mathcal{U}_{SM}$ which is continuous and a limit point $\eta_{\delta}(dx)$ in $\mathcal{P}(\mathbb{R}^d)$ of the invariant probability measures

 $\eta^{\varepsilon}_{\delta}(dx)$ of the process $X^{\varepsilon}_{\delta}(\cdot)$ given by (2.1) corresponding to $u_{\delta}(\cdot)$ such that

$$\iint \bar{r}(x,v)u_{\delta}(x)(dv)\eta_{\delta}(dx) \leq \inf_{x \in \mathbb{R}^d} \rho(x,u(\cdot)) + \delta.$$

Theorem 2.1. Assume (A1), (L) and (H1) or (H2). Then

$$\liminf_{\varepsilon \to 0} \rho_{\varepsilon}(x, U^{\varepsilon}(\cdot)) = \rho^*, x \in \mathbb{R}^d,$$

where $U^{\varepsilon}(\cdot)$ is an ergodic optimal control for (2.1);(2.2).

Proof. Let $(X_{\varepsilon}^{*}(\cdot), U_{\varepsilon}^{*}(\cdot))$ be an optimal ergodic stationary pair and $\pi^{\varepsilon} \in \mathcal{P}(\mathbb{R}^{d} \times \mathbb{U})$ be the corresponding ergodic ocupation measure for (2.1); (2.2). Using (A1), it follows that the laws of $(X_{\varepsilon}^{*}(\cdot), U_{\varepsilon}^{*}(\cdot))$ is tight and hence has a limit point $(X(\cdot), U(\cdot))$. Let the convergence be along the subsequence $\{\varepsilon_n\}$. One can see that $(X(\cdot), U(\cdot))$ is a stationary admissible pair for (1.1). Let π be its ergodic occupation measure, and hence π^{ε} converges weakly to π along the same subsequence $\{\varepsilon_n\}$. Thus we have

$$\lim_{n \to \infty} \rho_{\varepsilon_n}(x, U^*_{\varepsilon_n}(\cdot)) = \lim_{n \to \infty} \iint \bar{r}(x, u) \pi^{\varepsilon_n}(dx du) = \iint \bar{r}(x, u) \pi(dx du)$$

Let \mathcal{G}^* denote the set of all limit points of $\{\pi^{\varepsilon}\}$. Then from above, it follows that

(2.3)
$$\liminf_{\varepsilon \to 0} \rho_{\varepsilon}(x, U^{\varepsilon}(\cdot)) = \inf_{\pi \in \mathcal{G}^{*}} \iint \bar{r}(x, u) \pi(dx du) := \rho_{inf}^{*},$$
$$\limsup_{\varepsilon \to 0} \rho_{\varepsilon}(x, U^{\varepsilon}(\cdot)) = \sup_{\pi \in \mathcal{G}^{*}} \iint \bar{r}(x, u) \pi(dx du) := \rho_{sup}^{*}.$$

Now assume (H1). Let $(X^*(\cdot), U^*(\cdot))$ be an optimal ergodic pair as in Theorem 1.2 and $u^*(\cdot)$ be a corresponding stationary Markov control. Then $\pi^*(dxdu) = u^*(x)(du)\eta^*(dx) \in \mathcal{G}$ for some invariant probability distribution $\eta^*(dx)$ of $X^*(\cdot)$. Let $X^{\varepsilon}(\cdot)$ be the solution to (2.1) corresponding to $u^*(\cdot)$ with initial law $X^*(0)$. Using (L), a unique invariant probability measure $\eta^{\varepsilon}(dx)$ of $X^{\varepsilon}(\cdot)$ exists. Then $\pi^{\varepsilon}(dxdu) = u^*(x)(du)\eta^{\varepsilon}(dx)$ is an ergodic occupation measure of $(X^{\varepsilon}(\cdot), u^*(\cdot))$. In view of (H1), $\eta^*(dx)$ is a limit point of $\eta^{\varepsilon}(dx)$ and hence $\pi^*(dxdu)$ is a limit point of $\pi^{\varepsilon}(dxdu)$. Let $\pi^{\varepsilon_n} \to \pi^*$ in $\mathcal{P}(\mathbb{R}^d \times \mathbb{U})$ as $n \to \infty$. Since

$$\rho_{\varepsilon}(x, U^{\varepsilon}(\cdot)) \leq \iint \bar{r}(x, u) \pi^{\varepsilon}(dx du),$$

by letting $n \to \infty$, it follows that

$$\liminf_{\varepsilon \to 0} \rho_{\varepsilon}(x, U^{\varepsilon}(\cdot)) \leq \lim_{n \to \infty} \iint \bar{r}(x, u) \pi^{\varepsilon_n}(dx du) = \iint \bar{r}(x, u) \pi^*(dx du) = \rho^{**} = \rho^*.$$

The last equality above is due to Theorem 1.2. Hence

(2.4)
$$\rho^{**} \le \rho_{inf}^* \le \rho^{**}.$$

Hence using (2.3) and (2.4), we have

$$\liminf_{\varepsilon \to 0} \rho_{\varepsilon}(x, U^{\varepsilon}(\cdot)) = \rho^*.$$

Now assume (H2). Let $u^*(\cdot)$ be as above. For $\delta > 0$, there exists $u^*_{\delta}(\cdot) \in \mathcal{U}_{SM}$, continuous and $\eta_{\delta}(dx) \in \mathcal{P}(\mathbb{R}^d)$ such that

$$\iint \bar{r}(x,v)u_{\delta}^{*}(x)(dv)\eta_{\delta}(dx) \leq \rho(x,u_{\delta}^{*}(\cdot)) + \delta, x \in \mathbb{R}^{d}.$$

Let $X_{\delta}^{\varepsilon}(\cdot)$ be the solution to (2.1) corresponding to $u_{\delta}^{\varepsilon}(\cdot)$ with initial law $X^{*}(0)$. Using (L), a uniqu invariant probability measure $\eta_{\delta}^{\varepsilon}(dx)$ of $X_{\delta}^{\varepsilon}(\cdot)$ exists. Then $\pi_{\delta}^{\varepsilon}(dxdu) = u_{\delta}^{*}(x)(du)\eta_{\delta}^{\varepsilon}(dx)$ is an ergodic occupation measure of $(X_{\delta}^{\varepsilon}(\cdot), u_{\delta}^{\varepsilon}(\cdot))$. Consider

$$\liminf_{\varepsilon \to 0} \rho_{\varepsilon}(x, U^{\varepsilon}(\cdot)) \leq \lim_{n \to \infty} \iint \bar{r}(x, u) \pi_{\delta}^{\varepsilon_n}(dx du) = \iint \bar{r}(x, u) u_{\delta}^*(x)(dv) \eta_{\delta}(dx) \leq \rho^* + \delta.$$

Since $\delta > 0$ is arbitrary, the proof is completed. \Box

Remark 2.2. (i) In (H1), if $\eta(dx)$ is the limit of $\eta^{\varepsilon}(dx)$ or in (H2) $\eta_{\delta}(dx)$ is the limit of $\eta^{\varepsilon}_{\delta}(dx)$, then in Theorem 2.1, lim inf becomes lim.

(ii) We only need to assume (H2) for an optimal $u^*(\cdot)$ in Theorem 2.1.

Theorem 2.3. Assume (A1) and (L). Then there exists $U^*(\cdot) \in U$ and a stationary process $X^*(\cdot)$ corresponding to $U^*(\cdot)$ satisfying (1.1) such that

$$\rho(x, U^*(\cdot)) \le \rho(x, U(\cdot))$$
 for all $U(\cdot) \in \mathcal{U}, x \in \operatorname{supp}(\eta^*)$,

where η^* is the law of $X^*(0)$. More over

$$\rho^* = \inf_{x \in \mathbb{R}^d} \rho^*_{\mathcal{U}}(x).$$

Proof. Using (A1), i.e., the map $(x, U) \mapsto \mathcal{L}^U \hat{V}(x)$ from $\mathbb{R}^d \times \mathbb{U}$ is inf-compact for some positive inf-compact $\hat{V} \in C^2(\mathbb{R}^d)$, from Theorem 7.2.1, p.254, [1], there exists an optimal pair $(X^*(\cdot), U^*(\cdot))$, with $U^*(t) = u^*(X^*(t)), t \ge 0$ and $u^* \in \mathcal{U}_{SM}$. i.e. (2.5)

$$\rho^* = \inf_{(X(\cdot),U(\cdot))} \liminf_{t \to \infty} \frac{1}{t} E\left[\int_0^t r(X(s),U(s))ds\right] = \liminf_{t \to \infty} \frac{1}{t} E\left[\int_0^t r(X^*(s),U^*(s))ds\right]$$

where infimum is over all admissible pairs of (1.1). For the presribed control $U^*(\cdot)$, let $X(x; \cdot)$ denote the solution to (1.1) with initial condition X(x; 0) = x. Then from the fact that conditional law of $\{X^*(t) : 0 \le t < \infty\}$ given $X^*(0) = x$ is same as the law of $\{X(x; t) : 0 \le t < \infty\}$, we have for each t > 0,

$$E\left[\int_{0}^{t} r(X^{*}(s), U^{*}(s))ds\right] = \int_{\mathbb{R}^{d}} E\left[\int_{0}^{t} r(X^{*}(s), U^{*}(s))ds \Big| X^{*}(0) = x\right] \eta^{*}(dx)$$
$$= \int_{\mathbb{R}^{d}} E\left[\int_{0}^{t} r(X(x;s), U^{*}(s))ds\right] \eta^{*}(dx),$$

where $\eta^*(dx)$ denote the Law of $X^*(0)$. Hence using Fatou's lemma, we get,

$$\begin{split} \rho^* &= \liminf_{t \to \infty} \int_{\mathbb{R}^d} \frac{1}{t} E\Big[\int_0^t r(X(x;s), U^*(s)) ds\Big] \eta^*(dx) \\ &\geq \int_{\mathbb{R}^d} \Big(\liminf_{t \to \infty} \frac{1}{t} E\Big[\int_0^t r(X(x;s), U^*(s)) ds\Big]\Big) \eta^*(dx) \ = \ \int_{\mathbb{R}^d} \rho(x, U^*(\cdot)) \eta^*(dx). \end{split}$$

Now from the definition of ρ^* , we have $\rho^* \leq \rho(x, U^*(\cdot))$, for all $x \in \mathbb{R}^d$. Combining the above inequalities, we get $\rho^* = \rho(x, U^*(\cdot))$ a.s. (η^*) . Thus we get,

(2.6)
$$\rho^* = \inf_{x \in \mathbb{R}^d} \inf_{U(\cdot) \in \mathcal{U}} \rho(x, U(\cdot)).$$

Observe that, we can take $X(x; \cdot)$ in the above proof as a Markov process, since using Theorem 6.4.16, page 241 of [1], there exists a Markov process in the marginal class of $X(x; \cdot)$. Let $\eta_t^x, t > 0$ denote the family of emipirical measures of $X(x; \cdot)$, i.e.

$$\int f(y)\eta_t^x(dy) = \frac{1}{t}E\Big[\int_0^t f(X(x;s))ds, \ f \in C_b(\mathbb{R}^d)\Big]$$

For $x \in \mathbb{R}^d$, let η^x be a limit point of η^x_t . Set $T_t f(x) = Ef(X(x;t)), f \in C_b(\mathbb{R}^d)$. Then one can see that $T_t f$ is Lipschitz continuous for all $f \in C^2_b(\mathbb{R}^d)$, see Lemma .11. Hence for $f \in C^2_b(\mathbb{R}^d)$,

$$\int T_t f(x) \eta^x(dx) = \lim_{n \to \infty} \int T_t f(x) \eta^x_{t_n}(dx) = \lim_{n \to \infty} \frac{1}{t_n} \int_0^{t_n} T_{s+t} f(x) ds$$
$$= \lim_{n \to \infty} \frac{1}{t_n} \int_0^{t_n+t} T_s f(x) ds - \lim_{n \to \infty} \frac{1}{t_n} \int_0^t T_s f(x) ds = \int f(x) \eta^x(dx)$$

Hence η^x is an invariant distribution of $X(x; \cdot)$. Since $X^*(\cdot)$ and $X(x; \cdot)$ has the same Markov semigroup, it follows from Theorem 5.1, [11] that either $\eta^x = \eta^*$ or η^x and η^* are singular to each other.

Set

(2.7)
$$D_0 = \bigcup_{\eta^* \in \mathcal{H}^*} \Big\{ x \in \mathbb{R}^d \, \Big| \, \int f(y) \eta^x(dy) = \int f(y) \eta^*(dy) \text{ for all } f \in C_b(\mathbb{R}^d) \Big\},$$

where

(2.8)
$$\mathcal{H}^* = \left\{ \eta^* \in \mathcal{P}(\mathbb{R}^d) \, \middle| \, \eta^* \text{ satisfies } \eta^*(dx) = \pi^*(dx, \mathbb{U}), \text{ for some} \\ \pi^* \in \operatorname{argmin}_{\pi \in \mathcal{G}} \iint \bar{r}(x, u) \pi(dx du) \right\}.$$

Theorem 2.4. Assume (A1), (L) and that

$$\bar{r}(x,u) = r_1(x) + \bar{r}_2(u), \ x \in \mathbb{R}^d, u \in \mathbb{U}.$$

Then $U^*(\cdot) \in \mathcal{U}$ given in Theorem 2.3 satisfies

$$\rho(x, U^*(\cdot)) \le \rho(x, U(\cdot)) \text{ for all } U(\cdot) \in \mathcal{U}, x \in D_0.$$

More over, if $D_0 \subset \mathbb{R}^d$, then the above inequality need not hold for $x \notin D_0$.

Proof. For $x \in D_0$, let $X(x; \cdot)$ denote the solution to (1.1) corresponding to $U^*(\cdot)$ and initial condition x. Then

$$\rho(x, U^*(\cdot)) = \liminf_{t \to \infty} \frac{1}{t} E \Big[\int_0^t r(X(x; s), U^*(s)) ds \Big]$$

$$= \liminf_{t \to \infty} \frac{1}{t} \Big\{ E \Big[\int_0^t r_1(X(x; s)) ds \Big] + E \Big[\int_0^t \int_{\mathbb{U}} \bar{r}_2(u) U^*(s)(du) ds \Big] \Big\}$$

$$\leq \int_{\mathbb{R}^d} r_1(x) \eta^*(dx) + \int_{\mathbb{R}^d} \int_{\mathbb{U}} \bar{r}_2(u) \pi^*(dxdu) = \rho^*.$$

Since $\rho^* \leq \rho(x, U(\cdot))$ for all $U(\cdot) \in \mathcal{U}$, it follows that

$$\rho^* = \rho(x, U^*(\cdot)), x \in D_0.$$

For $x \notin D_0$, for any $U^*(\cdot)$ which is an ergodic optimal stationary control, the corresponding η^x is singular to $\eta^* \in \mathcal{H}^*$. Hence when r_1 satisfies argmax $r_1(x) \cap \bigcup_{\eta^* \in \mathcal{H}^*} \operatorname{supp}(\eta^*) = \emptyset$, we get for $x \in D_0^c$ satisfying

$$\min_{\operatorname{supp}(\eta_x)} r_1 \ge \max_{\operatorname{supp}(\eta^*)} r_1,$$

$$\rho(x, U^*(\cdot)) = \liminf_{t \to \infty} \frac{1}{t} E \Big[\int_0^t r(X(x; s), U^*(s)) ds \Big]$$
$$= \int_{\mathbb{R}^d} r_1(x) \eta^x(dx) + \iint \bar{r}_2(u) \pi^*(dx du) > \rho^*,$$

where η^x is the limit point corresponding to the liminf. This completes the proof.

3. Degenerate Ergodic control : Asymptotically Flat Diffusion

In this section, we assume (A1) with K < 0, i.e. the controlled diffusions are asymptotically flat, see Lemma 7.3.7, p.257 of [1]. We have the following result from [1], Theorem 7.3.7, p.257, Theorem 7.3.9, p.259, Theorem 7.3.10, p.260.

Theorem 3.1. Assume (A1) with K < 0. Then there exists $U^*(\cdot) \in \mathcal{U}_{SM}$ such that

$$\rho^* = \rho_{\mathcal{U}}^*(x) = \rho(x, U^*(\cdot)), x \in \mathbb{R}^d.$$

Also there exists $\varphi \in C^{0,1}(\mathbb{R}^d)$ such that $(\rho^*, \varphi) \in \mathbb{R} \times C^{0,1}(\mathbb{R}^d)$ is a viscosity solution to the HJB equation

$$\rho = \inf_{U \in \mathcal{P}(\mathbb{U})} [\langle m(x,U), \nabla \varphi \rangle + r(x,U)] + \frac{1}{2} \operatorname{trace}(a(x)\nabla^2 \varphi), x \in \mathbb{R}^d.$$

More over, if $(\rho, \psi) \in \mathbb{R} \times C^{0,1}(\mathbb{R}^d)$ is a viscosity solution to the HJB equation

$$\rho = \inf_{U \in \mathcal{P}(\mathbb{U})} [\langle m(x, U), \nabla \psi \rangle + r(x, U)] + \frac{1}{2} \operatorname{trace}(a(x) \nabla^2 \varphi), x \in \mathbb{R}^d,$$

then $\rho = \rho^*$.

i.e., as opposed to the non degenerate case, it is not known whether any minimizing selector is an optimal stationary Markov control. Also Theorem 3.1, only guarantee uniqueness of the value ρ^* but not $\varphi(\cdot)$. Using small noise perturbation to a specific example, first we illustrate what more one can expect.

Lemma 3.2. Assume (A1). For a prescribed control $U(\cdot) \in \mathcal{U}$, let $X^{\varepsilon}(\cdot), X(\cdot)$ denote respectively, solutions to (2.1), (1.1) with initial condition $x \in \mathbb{R}^d$. Then for $t \geq 0$,

$$E\|X^{\varepsilon}(t) - X(t)\|^2 \leq \begin{cases} \frac{\varepsilon^2}{2K}(e^{2Kt} - 1) & \text{if } K \neq 0\\ \varepsilon^2 t & \text{if } K = 0. \end{cases}$$

Proof. We have

$$X^{\varepsilon}(t) - X(t) = \int_0^t (m(X^{\varepsilon}(s), U(s)) - m(X(s), U(s))) ds + \int_0^t (\sigma_{\varepsilon}(X^{\varepsilon}(s)) - \sigma(X(s))) dW(s) d$$

Using Itô's formula we get

$$d\|X^{\varepsilon}(t) - X(t)\|^{2} = 2\sum_{i=1}^{d} (m_{i}(X^{\varepsilon}(t), U(t)) - m_{i}(X(t), U(t)))(X_{i}^{\varepsilon}(t) - X_{i}(t))dt$$

$$(3.1) + \sum_{i,j=1}^{d} (\sigma_{\varepsilon}^{ij}(X^{\varepsilon}(t) - \sigma^{ij}(X(t)))^{2}dt$$

$$+ 2\sum_{i,j=1}^{d} (X_{i}^{\varepsilon}(t) - X_{i}(t))(\sigma_{\varepsilon}^{ij}(X^{\varepsilon}(t) - \sigma^{ij}(X(t)))dW_{j}(t).$$

Using (A1) (ii), we get

$$E\|X^{\varepsilon}(t) - X(t)\|^{2} \leq E\|X^{\varepsilon}(s) - X(s)\|^{2} + 2K \int_{s}^{t} E\|X^{\varepsilon}(s') - X(s')\|^{2} ds'$$

(3.2) $+\varepsilon^{2}(t-s), \ 0 \leq s < t < \infty.$

Now using standard comparison theorem for odes, we get

$$E||X^{\varepsilon}(t) - X(t)||^2 \le h(t), \ 0 \le t < \infty,$$

where $h(\cdot)$ is the solution to the ode

$$\dot{h}(t) = 2Kh(t) + \varepsilon^2, \ h(0) = 0.$$

Hence for $t \geq 0$,

$$E\|X^{\varepsilon}(t) - X(t)\|^{2} \leq \begin{cases} \frac{\varepsilon^{2}}{2K}(e^{2Kt} - 1) & \text{if } K \neq 0\\ \varepsilon^{2}t & \text{if } K = 0. \end{cases}$$

| _ | - | |
|-------|---|--|
| | | |

Theorem 3.3. Assume (A1) with K < 0. (i) Following inequality holds.

$$-\hat{K}\varepsilon \leq \rho_{\varepsilon}(x, U_{\varepsilon}^{*}(\cdot) - \rho(x, U^{*}(\cdot))) \leq \hat{K}\varepsilon, \ x \in \mathbb{R}^{d},$$

for some constant \hat{K} which depends only on K and the Lipschitz constant of r, where $U_{\varepsilon}^{*}(\cdot), U^{*}(\cdot)$ are optimal control for (2.1);(2.2) and (1.1);(1.3) respectively. (ii) For $x \in \mathbb{R}^{d}$,

$$\lim_{\varepsilon \to 0} \rho(x, U_{\varepsilon}^*(\cdot)) = \rho(x, U^*(\cdot)).$$

Proof. Consider

$$\begin{split} \rho_{\varepsilon}^{*}(x) - \rho_{\mathcal{U}}^{*}(x) &\geq \lim_{t \to \infty} \frac{1}{t} E_{x} \Big[\int_{0}^{t} r(X^{\varepsilon}(s), U_{\varepsilon}^{*}(s)) ds \Big] - \liminf_{t \to \infty} \frac{1}{t} E_{x} \Big[\int_{0}^{t} r(X(s), U_{\varepsilon}^{*}(s)) ds \Big] \\ &\geq \liminf_{t \to \infty} \frac{1}{t} E \Big[\int_{0}^{t} (r(X^{\varepsilon}(s), U_{\varepsilon}^{*}(s)) - r(X(s), U_{\varepsilon}^{*}(s))) ds \Big] \\ &\geq \operatorname{Lip}(r) \liminf_{t \to \infty} \Big(-\frac{1}{t} \int_{0}^{t} E \| X^{\varepsilon}(s) - X(s) \| ds \Big) \\ &\geq -\operatorname{Lip}(r) \sqrt{\frac{\varepsilon}{2|K|}}, \end{split}$$

where $X^{\varepsilon}(\cdot), X(\cdot)$ denote the solutions of the sdes (2.1), (1.1) with initial condition $x \in \mathbb{R}^d$ corresponding to the control $U^*_{\varepsilon}(\cdot)$ in the prescribed form. The last inequality above follows from Lemma 3.2. Again consider

$$\begin{split} \rho_{\varepsilon}^{*}(x) - \rho_{\mathcal{U}}^{*}(x) &\leq \liminf_{t \to \infty} \frac{1}{t} E_{x} \Big[\int_{0}^{t} r(X^{\varepsilon}(s), U^{*}(s)) ds \Big] - \liminf_{t \to \infty} \frac{1}{t} E_{x} \Big[\int_{0}^{t} r(X(s), U^{*}(s)) ds \Big] \\ &\leq \limsup_{t \to \infty} \frac{1}{t} E \Big[\int_{0}^{t} (r(X^{\varepsilon}(s), U_{\varepsilon}^{*}(s)) - r(X(s), U_{\varepsilon}^{*}(s))) ds \Big] \\ &\leq \operatorname{Lip}(r) \limsup_{t \to \infty} \frac{1}{t} \int_{0}^{t} E \| X^{\varepsilon}(s) - X(s) \| ds \\ &\leq \operatorname{Lip}(r) \sqrt{\frac{\varepsilon}{2|K|}}, \end{split}$$

where $X^{\varepsilon}(\cdot), X(\cdot)$ denote the solutions of the sdes (2.1), (1.1) with initial condition $x \in \mathbb{R}^d$ corresponding to the control $U^*(\cdot)$ in the prescribed form and the last inequality follows from Lemma 3.2. This completes the proof of inequality in (i).

¿From the above calculation, we can see that

$$\rho_{\varepsilon}(x, U_{\varepsilon}^{*}(\cdot)) - \rho(x, U_{\varepsilon}^{*}(\cdot)) \ge -\operatorname{Lip}(r) \sqrt{\frac{\varepsilon}{2|K|}}.$$

Hence we have from (i),

$$\limsup_{\varepsilon \to 0} \rho(x, U_{\varepsilon}^{*}(\cdot)) \leq \rho(x, U^{*}(\cdot)), x \in \mathbb{R}^{d}.$$

Since $\rho(x, U_{\varepsilon}^{*}(\cdot)) \geq \rho(x, U^{*}(\cdot))$ for all $x \in \mathbb{R}^{d}$, (ii) follows.

4. Beyond Asymptotically flat diffusion

In this section, we go beyond the asymptotically flat diffusions framework. We assume that

Assumption (B). • There exists uniformly continuous $b_i = (b_i^1, \dots, b_i^d)$: $\mathbb{R}^d \to \mathbb{R}^d$ satisfying linear growth condition such that

$$b_1^i(x-y) < \bar{m}_i(x,u) - \bar{m}_i(y,u) \le b_2^i(x-y), \ x,y \in \mathbb{R}^d, u \in \mathbb{U},$$

where $b_i, i = 1, 2$ is such that

$$\dot{X}^{i}(t) = b_{i}(X^{i}(t)), i = 1, 2$$

has a unique stable equilibrium at 0 and \mathbb{R}^d is attracted to 0.

• There exist non-negative and inf-compact $h \in C(\mathbb{R}^d)$ and a constant k_0 satisfying

(4.1)
$$\mathcal{L}_{\epsilon,i}V(x) \le k_0 - h(x), \ \forall x \in \mathbb{R}^d,$$

where V is non-negative, inf-compact and $V \in C^2(\mathbb{R}^d)$, such that $\nabla^2 V$ is bounded,

(4.2)
$$\mathcal{L}_{\epsilon,i}\phi := \langle b_i(x), \nabla \phi \rangle + \frac{\varepsilon^2}{2} \operatorname{tr}(\hat{\sigma}(0)\hat{\sigma}(0)^T \nabla^2 \phi),$$

 $\hat{\sigma}_{\varepsilon}: \mathbb{R}^d \times \mathbb{R}^d \to \mathbb{R}^d \otimes \mathbb{R}^d \text{ defines the perturbation } \sigma_{\varepsilon} \text{ of } \sigma \text{ as given by} \\ \hat{\sigma}_{\varepsilon}(x, y) = \sigma(y) + \varepsilon \hat{\sigma}(x - y), \ x, y \in \mathbb{R}^d, \ \sigma_{\varepsilon}(x) = \hat{\sigma}_{\varepsilon}(x, x)$

and $\hat{\sigma} : \mathbb{R}^d \to \mathbb{R}^d \otimes \mathbb{R}^d$ is uniformly elliptic and Lipschitz continuous.

Assumption (C). The function r is bounded, and $b_i : \mathbb{R}^d \to \mathbb{R}^d$, $\hat{\sigma} : \mathbb{R}^d \to \mathbb{R}^d \otimes \mathbb{R}^d$ are bounded, smooth with bounded derivetives of order upto 2. Also satisfies

•

$$\lambda \|x\|^2 \le x^T \hat{\sigma}(0) \hat{\sigma}(0)^T x \le \Lambda \|x\|^2, x \in \mathbb{R}^d$$

for some $0 < \lambda \leq \Lambda$.

• There exists constants $\alpha > 0, \ 0 < \beta \leq 1$ such that

$$\limsup_{\|x\|\to\infty} \left[\alpha \Lambda + \frac{1}{\|x\|^{\beta}} \langle b_i(x), x \rangle \right] < 0.$$

We consider the small noise limit of the control problem with state dynamics given by

(4.3)
$$dX^{\varepsilon}(t) = m(X^{\varepsilon}(t), U(t))dt + \hat{\sigma}_{\varepsilon}(X^{\varepsilon}(t), X^{\varepsilon}(t))dW(t)$$

and cost criterion given by (2.2).

We will be using the following comparison theorem for multi dimensional sdes. The proof essentially follows from the proof of Theorem 1.1 of [10]. The key idea in the proof of Theorem 1.1 is application of Itô's formula to the difference of the processes under consideration which turns out be same as ours. So we omit the details. In the theorem below, we use $x \leq y, x, y \in \mathbb{R}^d$ for $x_i \leq y_i$ for all *i* where x_i, y_i respectively denote the *i*th component.

Theorem 4.1. Let $X(\cdot), Y(\cdot), Z(\cdot)$ be $\{\mathcal{F}_t\}$ -adapted processes with a.s. continuous paths on a complete probability space (Ω, \mathcal{F}, P) such that $\{\mathcal{F}_t\}$ satisfies the usual conditions. Further, let $X(\cdot), Y(\cdot)$ be pathwise solutions of the sdes

$$\begin{aligned} dX(t) &= a(t, X(t))dt + (Z(t) + \sigma(X(t)))dW(t), \\ dY(t) &= b(t, Y(t))dt + (Z(t) + \sigma(Y(t)))dW(t), \end{aligned}$$

where $a = (a_1, \ldots, a_d), b = (b_1, \ldots, b_d) : [0, \infty) \times \mathbb{R}^d \to \mathbb{R}^d$, are continuous functions, $\sigma : \mathbb{R}^d \to \mathbb{R}^d \otimes \mathbb{R}^d$ is Lipschitz continuous and $W(\cdot)$ is a $\{\mathcal{F}_t\}$ -Wiener process in \mathbb{R}^d . If

$$a_i(t,x) < b_i(t,y)$$
 whenever $x_i = y_i, x_j \leq y_j, j \neq i$

and $X(0) \le Y(0)$ a.s., then $P(X(t) \le Y(t), t \ge 0) = 1$.

Consider for $U(\cdot) \in \mathcal{U}$,

(4.4)
$$dY_i^{\epsilon}(t) = b_i(Y_i^{\epsilon}(t))dt + (\sigma(X^{\epsilon}(t) - \sigma(X(t)) + \epsilon\hat{\sigma}(0))dW(t), \ i = 1, 2,$$

where the processes $X^{\varepsilon}(\cdot)$ and $X(\cdot)$ are given by the solutions of the sdes (4.3) and (1.1) corresponding to $U(\cdot)$. Following observation is kept in mind for the mext Lemma. Given $U(\cdot) \in \mathcal{U}$, the laws of $X^{\varepsilon}(\cdot)$ is tight and any limit point $\hat{X}(\cdot)$ in law is a solution to the sde (1.1) corresponding to $U(\cdot)$ when $U(\cdot)$ is either a prescribed control or a continuous Markov control. When $U(\cdot)$ is a continuous Markov control, then there may be multiple limit points which are all weak solutions of (1.1).

Set for $z = (y, x_1, x_2) \in \mathbb{R}^{3d}, u \in \mathcal{U}_{SM}$,

$$(4.5) \quad \mathcal{L}_{Z}^{\varepsilon}f(z) = \mathcal{L}_{\varepsilon,i}f + \langle m(x_{1}, u(x_{2})), \nabla_{x_{1}}f \rangle + \langle m(x_{2}, u(x_{2})), \nabla_{x_{2}}f \rangle + \mathcal{L}_{Z,\varepsilon}^{1}f(z),$$

where

$$\mathcal{L}_{Z,\varepsilon}^{1}f = \frac{1}{2}\operatorname{trace}(\sigma(x_{1},x_{2})\sigma(x_{1},x_{2})^{T}\nabla_{y}^{2}f) + \varepsilon\operatorname{trace}(\sigma(x_{1},x_{2})\hat{\sigma}(0)^{T}\nabla_{y}^{2}f) + \frac{1}{2}\operatorname{trace}(\sigma(x_{1})\sigma(x_{1})^{T}\nabla_{x_{1}}^{2}f) + \frac{1}{2}\operatorname{trace}(\sigma(x_{2})\sigma(x_{2})^{T}\nabla_{x_{2}}^{2}f) + \operatorname{trace}(\sigma(x_{1})\sigma(x_{2})^{T}\nabla_{x_{1}x_{2}}^{2}f) + \operatorname{trace}(\sigma(x_{1},x_{2})\sigma(x_{1})^{T}\nabla_{x_{1}y}^{2}f) + \varepsilon\operatorname{trace}(\hat{\sigma}(0)\sigma(x_{1})^{T}\nabla_{x_{1}y}^{2}f) + \operatorname{trace}(\sigma(x_{1},x_{2})\sigma(x_{2})^{T}\nabla_{x_{2}y}^{2}f) + \varepsilon\operatorname{trace}(\hat{\sigma}(0)\sigma(x_{2})^{T}\nabla_{x_{2}y}^{2}f), f \in C_{b}^{2}(\mathbb{R}^{3d}),$$

and $\mathcal{L}_{\varepsilon,i}$ is given by (4.2).

Lemma 4.2. Assume (A1) and (B). For $U(\cdot) \in \mathcal{U}$, given by $U(t) = u(X(t)), t \geq 0$, where u is a measurable map such that $(Y_i^{\varepsilon}(\cdot), X^{\varepsilon}(\cdot), X(\cdot))$ be solutions of (4.4), (4.3) and (1.1) respectively satisfying $X^{\varepsilon}(\cdot) \to X(\cdot)$ in law along a subsequence as $\varepsilon_n \to 0$. Then any limit point $\eta_{\varepsilon_n,i}$ of the empirical measures of $Y_i^{\varepsilon_n}(\cdot)$ converges weakly to δ_0 .

Proof. Fix i = 1 and suppress n from ε_n and we denote $\mathcal{L}_{\epsilon,1}$ by \mathcal{L}_{ϵ} . Set $Z^{\varepsilon}(t) = (Y_1^{\varepsilon}(t), X^{\varepsilon}(t), X(t))^T, t \geq 0$ and $\sigma(x_1, x_2) = \sigma(x_1) - \sigma(x_2), x_1, x_2 \in \mathbb{R}^d$. Then the infinitesimal generator of $Z^{\varepsilon}(\cdot)$ is given by the differential operator $\mathcal{L}_Z^{\varepsilon}$ defined in (4.5).

Consider the family of empirical measures $\mu_t^{\varepsilon} \in \mathcal{P}(\mathbb{R}^{3d})$ of $Z^{\varepsilon}(\cdot)$, i.e.,

$$\iiint_{\mathbb{R}^{3d}} f(z)\mu_t^{\varepsilon}(dz) = \frac{1}{t}E\Big[\int_0^t f(Z_1^{\varepsilon}(s))ds\Big], \ f \in C_b(\mathbb{R}^{3d}), \ t > 0.$$

Let τ_n denote the exit time of the process $Z^{\varepsilon}(\cdot)$ from B_n , the ball in \mathbb{R}^{3d} of radius n centered at the origin. Define

$$\hat{V}(z) = V(y) + V(x_1) + V(x_2), z = (y, x_1, x_2) \in \mathbb{R}^{3d},$$

where V is the Lyapunov function given in (B). Then observe that

$$\mathcal{L}_{Z}^{\varepsilon}\hat{V}(z) = \mathcal{L}_{\epsilon}V(y) + \mathcal{L}_{\epsilon}^{1}V(x_{1}) + \mathcal{L}_{\epsilon}^{2}V(x_{2}),$$

where

$$\mathcal{L}_{\epsilon}^{i}f = \langle m(x_{i}, u(x_{2})), \nabla f \rangle + \frac{1}{2} \operatorname{trace}(\sigma(x_{i})\sigma(x_{i})^{T} \nabla^{2} f), \ f \in C^{2}(\mathbb{R}^{d}), \ i = 1, 2.$$

Then using Itô-Dynkin's formula, we get

$$\begin{split} E_{z}[\hat{V}((Z^{\varepsilon}(\tau_{n} \wedge t))] &= \hat{V}(z) + E_{z}\Big[\int_{0}^{\tau_{n} \wedge t} \mathcal{L}_{Z}^{\varepsilon} \hat{V}(Z^{\varepsilon}(s))ds\Big] \\ &\leq V(z) + K_{0}E_{z}[\tau_{n} \wedge t] - E_{z}\Big[\int_{0}^{\tau_{n} \wedge t} h(Y_{1}^{\varepsilon}(s))ds\Big] \\ &- E_{z}\Big[\int_{0}^{\tau_{n} \wedge t} h(X^{\varepsilon}(s))ds\Big] - E_{z}\Big[\int_{0}^{\tau_{n} \wedge t} h(X(s))ds\Big], \end{split}$$

where $Z^{\varepsilon}(0) = z$, the constant $K_0 > 0$ depends only on k_0 and the bounds of $\sigma, \hat{\sigma}$, and $\nabla^2 V$. Now by letting $n \to \infty$ with the help of Monotone convergence theorem, we get for each R > 0,

$$E_{z}\left[\int_{0}^{t} (h(Y_{1}^{\varepsilon}(s)) + h(X^{\varepsilon}(s) + h(X(s))I_{\parallel Z^{\varepsilon}(s)\parallel \ge R}ds\right] \le V(z) + K_{0}t.$$

This implies

(4.6)
$$\frac{1}{t} \int_0^t P\Big(\|Z^{\varepsilon}(s)\| \ge R \Big) ds \le \frac{K_0 t + V(z)}{3t \inf_{\|x\| \ge R} h(x)}$$

Since $\inf_{\|x\|\geq R} h(x) \to \infty$ as $R \to \infty$, from (4.6), the tightness of the empirical measures $\{\mu_t^{\varepsilon} : t \geq 0\}$ follows for each $\varepsilon > 0$.

Let $\mu^{\varepsilon} \in \mathcal{P}(\mathbb{R}^{3d})$ be a limit point of $\{\mu_t^{\varepsilon} : t \ge 0\}$ for each $\varepsilon > 0$. Then it follows that

(4.7)
$$\iiint \mathcal{L}_Z^{\varepsilon} f(z) \mu^{\varepsilon}(dz) = 0 \text{ for all } f \in C_c^{\infty}(\mathbb{R}^{3d}).$$

Hence, μ^{ε} is an invariant probability measure for $Z^{\varepsilon}(\cdot)$, see Lemma .12.

Again from (4.6), it follows that $\{\mu^{\varepsilon}|\varepsilon > 0\}$ is a tight family and let $\mu \in \mathcal{P}(\mathbb{R}^{3d})$ be a limit point of it. For each $f \in C_c^{\infty}(\mathbb{R}^{3d})$, it is easy to see that $\mathcal{L}_Z^{\varepsilon}f \to \mathcal{L}_Z^0f$ uniformly, where \mathcal{L}_Z^0 is the differential operator given by substituting $\varepsilon = 0$ in $\mathcal{L}_Z^{\varepsilon}$. Note that for $f \in C_b^2(\mathbb{R}^{2d})$, we have

(4.8)

$$\mathcal{L}_{Z}^{0}f(x_{1}, x_{2}) = \langle m(x_{1}, u(x_{2}), \nabla_{x_{1}}f) + \frac{1}{2}\operatorname{trace}(\sigma(x_{1})\sigma(x_{1})^{T}\nabla_{x_{1}}^{2}f) + \langle m(x_{2}, u(x_{2}), \nabla_{x_{2}}f) + \frac{1}{2}\operatorname{trace}(\sigma(x_{1})\sigma(x_{1})^{T}\nabla_{x_{1}}^{2}f) + \operatorname{trace}(\sigma(x_{1})\sigma(x_{2})^{T}\nabla_{x_{1}x_{2}}^{2}f)$$

which defines the infinitesimal generator of the process $(X(\cdot), \hat{X}(\cdot))$ given by

(4.9)
$$dX(t) = m(X(t), u(X(t)))dt + \sigma(X(t))dW(t),$$

(4.10)
$$d\hat{X}(t) = m(\hat{X}(t), u(X(t)))dt + \sigma(\hat{X}(t))dW(t).$$

Since sde (4.10) has a unique solution given by $X(\cdot)$ for any given solution $X(\cdot)$ of (4.9) corresponding to any given initial condition $x \in \mathbb{R}^d$, it follows that \mathcal{L}_Z^0 given in (4.8) defines the infinitesimal generator for $(X(\cdot), X(\cdot))$.

For $f \in C_c^{\infty}(\mathbb{R}^{3d})$, by letting $\varepsilon \to 0$ in (4.7), it follows that

(4.11)
$$\iiint \mathcal{L}_Z^0 f(z) \mu(dz) = 0$$

By disintegrating μ^{ε}, μ , we have

$$\mu^{\varepsilon}(dydx_{1}dx_{2}) = g^{\varepsilon}(dy|x_{1}, x_{2})\nu^{\varepsilon}(dx_{1}dx_{2}), \ \mu(dydx_{1}dx_{2}) = g(dy|x_{1}, x_{2})\nu(dx_{1}dx_{2}),$$

where ν^{ε} is an invariant probability measures of $(X^{\varepsilon}(\cdot), X(\cdot))$. Also from (4.11), it follows that

$$\iint \mathcal{L}_Z^0 f(x_1, x_2) \nu(dx_1 dx_2) = 0, \text{ for all } f \in C_c^\infty(\mathbb{R}^{2d}).$$

Hence ν is an invariant measure for the process $(X(\cdot), X(\cdot))$. Therefore, ν is supported in $\{(x_1, x_2)|x_1 = x_2\}$. Hence (4.11) takes the form

(4.12)
$$\int \langle b_1(y), \nabla f(y) \rangle \eta(dy) = 0 \text{ for all } f \in C_c^{\infty}(\mathbb{R}^d).$$

where $\eta(dy)$ comes from the distintegration of μ given by

$$\mu(dydx_1dx_2) = h(dx_1dx_2|y)\eta(dy)$$

and clearly $\eta_{\varepsilon,1} \to \eta$ as $\varepsilon \to 0$. From (4.12), we get that $\eta(dy)$ is an invariant probability measure for

$$dY(t) = b_1(Y(t))dt.$$

and hence $\eta(dy) = \delta_0(dy)$, using assumption (B). In particular, the conclusion of Lemma follows.

Remark 4.3. • In Lemma 4.2, when u is continuous, then if $X(\cdot)$ is limit point in law of $X^{\varepsilon}(\cdot)$, then one can see that $X(\cdot)$ solves the sde (1.1) corresponding to the stationary Markov control $u(\cdot)$. But this is not known to be true when $u(\cdot)$ is just measurable.

If $u(\cdot)$ is Lipschitz continuous, then the sde (1.1) has a unique solution and hence $X^{\varepsilon}(\cdot)$ converges in law to the solution of the sde (1.1).

• Even when u is smooth, the empirical measures of $Y_i^{\varepsilon}(\cdot)$ can have multiple limit points but Lemma 4.2 guarantees that all these limit points converges to δ_0 as $\varepsilon \to 0$.

For
$$R > 0$$
, define $h_R(s) = \begin{cases} \operatorname{Lip}(r)s, & |s| < R\\ \operatorname{Lip}(r)R, & |s| \ge R. \end{cases}$

For $u \in \mathcal{U}_{SM}$, if $X(\cdot)$ is a solution to the sde (1.1) with initial condition X(0) = x, then

$$\rho(x, U(\cdot)) = \liminf_{t \to \infty} \frac{1}{t} E_x \Big[\int_0^t r(X(s), U(s)) ds \Big],$$

where $U(t) = u(X(t)), t \ge 0$ is in prescribed form and note that $X(\cdot)$ is a unique solution to the sde (1.1) corresponding to the prescribed control $U(\cdot)$. Now let $X^{\varepsilon}(\cdot)$ denote a unique solution to the sde (4.3) corresponding to $U(\cdot)$ with initial condition $X^{\varepsilon}(0) = x$, then $X^{\varepsilon}(\cdot)$ converges in law to $X(\cdot)$ as $\varepsilon \to 0$. Hence,

$$\begin{aligned} \frac{1}{t}E\Bigg[\int_{0}^{t}(r(X^{\varepsilon}(s),U(s))-r(X(s),U(s)))ds\Bigg]\\ &=\frac{1}{t}E\Bigg[\int_{0}^{t}(r(X^{\varepsilon}(s),U(s))-r(X(s),U(s)))I_{\|X^{\varepsilon}(s)-X(s)\|< R}ds\Bigg]\\ &+\frac{1}{t}E\Bigg[\int_{0}^{t}(r(X^{\varepsilon}(s),U(s))-r(X(s),U(s)))I_{\|X^{\varepsilon}(s)-X(s)\|\geq R}ds\Bigg]\\ &\leq\frac{1}{t}E\Bigg[\int_{0}^{t}h_{R}(\|X^{\varepsilon}(s)-X(s)\|)ds\Bigg]\\ &+2\|r\|_{\infty}\frac{1}{t}\int_{0}^{t}P(\|X^{\varepsilon}(s)-X(s)\|\geq R)ds\\ &=:I_{1}(R)+I_{2}(R)\end{aligned}$$
(4.13)

Set $Y^{\varepsilon}(t) = X^{\varepsilon}(t) - X(t), t \ge 0$. Then $Y^{\varepsilon}(\cdot)$ is a solution to the sde

(4.14)
$$dY^{\varepsilon}(t) = (m(X^{\varepsilon}(t), U(t)) - m(X(t), U(t)))dt + [\sigma(X^{\varepsilon}(t)) - \sigma(X(t)) + \varepsilon\hat{\sigma}(Y^{\varepsilon}(t))]dW(t).$$

Using Theorem 4.1, we get

$$P(Y_1^{\varepsilon}(t) \le Y^{\varepsilon}(t) \le Y_2^{\varepsilon}(t) \text{ for all } t) = 1.$$

This implies

(4.15)
$$\|Y^{\varepsilon}\| \le \max\{\|Y_1^{\varepsilon}\|, \|Y_2^{\varepsilon}\|\} \text{ a.s.}$$

Since, $h_R(\cdot)$ is a non decreasing function, using (4.13), we get

$$(4.16) \qquad I_1(R) = \frac{1}{t}E\int_0^t h_R(\|Y^{\varepsilon}(s)\|)ds$$
$$\leq \max\left\{\frac{1}{t}E\int_0^t h_R(\|Y_1^{\varepsilon}(s)\|)ds, \frac{1}{t}E\int_0^t h_R(\|Y_2^{\varepsilon}(s)\|)ds\right\}$$
$$\leq \sum_{i=1}^2 \frac{1}{t}E\int_0^t h_R(\|Y_i^{\varepsilon}(s)\|)ds.$$

Also,

(4.17)
$$I_{2}(R) \leq 2 \|r\|_{\infty} \frac{1}{t} \int_{0}^{t} P(\max\{|Y_{1}^{\epsilon}(s)|, |Y_{2}^{\epsilon}(s)|\} \geq R) ds$$
$$\leq 2 \|r\|_{\infty} \sum_{i=1}^{2} \frac{1}{t} \int_{0}^{t} P(|Y_{i}^{\epsilon}(s)| \geq R) ds.$$

Let $\eta_{\epsilon,i}[u]$ be a limit point of empirical probability measures of $Y_i^\epsilon(\cdot)$ satisfying

$$\begin{split} \limsup_{t \to \infty} \frac{1}{t} E\Big[\int_0^t h_R(\|Y_i^{\varepsilon}(s)\|) ds\Big] &= \int h_R(\|x\|) \eta_{\epsilon,i}[u](dx),\\ \limsup_{t \to \infty} \frac{1}{t} \int_0^t P\big(\|Y_i^{\varepsilon}(s)\| \ge R\big) ds &\le \eta_{\epsilon,i}[u](B_R^c). \end{split}$$

Hence, we have

(4.18)
$$\limsup_{t \to \infty} I_1(R) \leq \sum_{i=1}^2 \int_{\mathbb{R}^d} h_R(\|x\|) \eta_{\epsilon,i}[u](dx),$$
$$\limsup_{t \to \infty} I_2(R) \leq 2\|r\|_{\infty} \sum_{i=1}^2 \eta_{\epsilon,i}[u](B_R^c).$$

Using Lemma 4.2, we get,

$$\begin{array}{lll} (4.1 \underset{\varepsilon \to 0}{\underset{t \to \infty}{\lim}} \limsup_{t \to \infty} I_1(R) & \leq & \lim_{\varepsilon \to 0} \sum_{i=1}^2 \int_{\mathbb{R}^d} h_R(\|x\|) \eta_{\epsilon,i}[u](dx) \ = & 0, \\ \\ & \lim_{\varepsilon \to 0} \limsup_{t \to \infty} I_2(R) & \leq & 2 \|r\|_{\infty} \lim_{\varepsilon \to 0} \sum_{i=1}^2 \eta_{\varepsilon,i}[u](B_R^c) = 0 \text{ because } \delta_0(B_R^c) = 0. \end{array}$$

Thus,

$$\begin{aligned}
\rho_{\varepsilon}^{*}(x) - \rho(x, U(\cdot)) &\leq \liminf_{t \to \infty} \frac{1}{t} E_{x} \Big[\int_{0}^{t} r(X^{\varepsilon}(s), U(s)) ds \Big] \\
&- \liminf_{t \to \infty} \frac{1}{t} E_{x} \Big[\int_{0}^{t} r(X(s), U(s)) ds \Big] \\
\end{aligned}$$

$$(4.20) &\leq \limsup_{t \to \infty} \frac{1}{t} E \Big[\int_{0}^{t} (r(X^{\varepsilon}(s), U(s)) - r(X(s), U(s))) ds \Big] \\
&\leq \sum_{i=1}^{2} \int_{\mathbb{R}^{d}} h_{R}(\|x\|) \eta_{\varepsilon,i}[u](dx) + 2\|r\|_{\infty} \sum_{i=1}^{2} \eta_{\varepsilon,i}[u](B_{R}^{c}), R > 0
\end{aligned}$$

Hence using equations (4.19) and observing that $\rho(x, U(\cdot)) = \infty$ if the sde (1.1) has no solution corresponding to the stationary Markov control $u(\cdot)$ with initial condition x, we arrive at the following lemma.

Lemma 4.4. Assume (A1) and (B). Then we have

$$\lim_{\varepsilon \to 0} \rho_{\varepsilon}^*(x) \leq \inf_{u(\cdot) \in \mathcal{U}_{SM}} \rho(x, u(\cdot)).$$

Set for $z = (y, x_1, x_2) \in \mathbb{R}^{3d}$,

(4.21)
$$\mathcal{L}_{Z}^{\varepsilon}f(z) = \mathcal{L}_{\varepsilon,i}f + \langle m(x_1, u(x_1)), \nabla_{x_1}f \rangle + \langle m(x_2, u(x_1)), \nabla_{x_2}f \rangle + \mathcal{L}_{Z,\varepsilon}^1f(z)$$

where $\mathcal{L}_{Z,\varepsilon}^1$ is given in (4.5).

Lemma 4.5. Assume (A1) and (B). For $U(\cdot) \in \mathcal{U}$, given by $U(t) = u(X^{\varepsilon}(t)), t \geq 0$, where $u(\cdot)$ is a smooth map such that $(Y_i^{\varepsilon}(\cdot), X^{\varepsilon}(\cdot), X_{\varepsilon}(\cdot))$ are solutions of (4.4), (4.3) and (1.1) respectively. Then any limit point $\eta_{\varepsilon_n,i}$ of the empirical measures of $Y_i^{\varepsilon_n}(\cdot)$ converges weakly to δ_0 .

Proof. Again, fix i = 1 and we denote $\mathcal{L}_{\epsilon,1}$ by \mathcal{L}_{ϵ} . Set $Z^{\varepsilon}(t) = (Y_1^{\varepsilon}(t), X^{\varepsilon}(t), X_{\varepsilon}(t))^T, t \ge 0$. Then the infinitesimal generator of $Z^{\varepsilon}(\cdot)$ is given by the differential operator $\mathcal{L}_Z^{\varepsilon}$ given in (4.21).

Using the smoothness of u and (A1), it follows that $(X^{\varepsilon}(\cdot), X_{\varepsilon}(\cdot))$ converges in law to $(X(\cdot), X(\cdot))$ given by

(4.22)
$$dX(t) = m(X(t), u(X(t)))dt + \sigma(X(t))dW(t).$$

Consider the family of empirical measures $\mu_t^{\varepsilon} \in \mathcal{P}(\mathbb{R}^{3d})$ of $Z^{\varepsilon}(\cdot)$ given by

$$\iiint_{\mathbb{R}^{3d}} f(z)\mu_t^{\varepsilon}(dz) = \frac{1}{t} E\Big[\int_0^t f(Z^{\varepsilon}(s))ds\Big], \ f \in C_b(\mathbb{R}^{3d}), \ t > 0$$

By repeating the arguments as in the proof of Lemma 4.2, the tightness of the empirical measures $\{\mu_t^{\varepsilon} : t > 0\}$ follows for each $\varepsilon > 0$.

Let $\mu^{\varepsilon} \in \mathcal{P}(\mathbb{R}^{3d})$ be a limit point of $\{\mu_t^{\varepsilon} : t \ge 0\}$ for each $\varepsilon > 0$. Then it follows that

(4.23)
$$\iiint \mathcal{L}_Z^{\varepsilon} f(z) \mu^{\varepsilon}(dz) = 0 \text{ for all } f \in C_c^{\infty}(\mathbb{R}^{3d}).$$

Hence, μ^{ε} is an invariant probability measure for $Z^{\varepsilon}(\cdot)$, see Appendix, Lemma .12.

Again from (4.6), it follows that $\{\mu^{\varepsilon}|\varepsilon > 0\}$ is a tight family and let $\mu \in \mathcal{P}(\mathbb{R}^{3d})$ be a limit point of it. For each $f \in C_c^{\infty}(\mathbb{R}^{3d})$, it is easy to see that $\mathcal{L}_Z^{\varepsilon}f \to \mathcal{L}_Z^0f$ uniformly, where \mathcal{L}_Z^0 is the differential operator given by substituting $\varepsilon = 0$ in $\mathcal{L}_Z^{\varepsilon}$.

Now repeating the arguments as in the proof of Lemma 4.2, i follows that $\eta_{\varepsilon,1} \to \delta_0$ as $\varepsilon \to 0$. This completes the proof.

(D) Assume that

$$\lim_{\varepsilon \to 0} \sup_{u \in \mathcal{U}_{SM}^{smooth}} \sup_{\eta_i \in \mathcal{H}_{\varepsilon,i}[u]} \left(\sum_{i=1}^2 \int_{\mathbb{R}^d} h_R(\|x\|) \eta_i(dx) + 2\|r\|_{\infty} \sum_{i=1}^2 \eta_i(B_R^c) \right) = 0,$$

where $\mathcal{H}_{\varepsilon,i}[u]$ denote the set of all invariant probability measure of $Y_i^{\varepsilon}(\cdot)$ given by (4.4) corresponding to the stationary Markov control $u(\cdot)$, $X^{\varepsilon}(\cdot)$ is given by (4.3) correponding to the stationary Markov control $u(\cdot)$ and $X(\cdot)$ denote the solution of the sde (1.1) corresponding to the control $u(X^{\varepsilon}(\cdot))$ and $\mathcal{U}_{SM}^{smooth}$ denote the set of all smooth stationary Markov controls for (4.3).

Theorem 4.6. Assume (A1), (B) and (D). There exists a sequence of admissible controls $U^{\varepsilon}(t) = u^{\varepsilon}(X^{\varepsilon}(t)), t \ge 0, u^{\varepsilon} \in \mathcal{U}_{SM}^{smooth}$ satisfying

(i) $U^{\varepsilon}(\cdot)$ is ε -optimal for the problem (4.3); (2.2) and (ii)

$$\lim_{\varepsilon \to 0} \rho_{\varepsilon}(x, U^{\varepsilon}(\cdot)) = \inf_{U(\cdot) \in \mathcal{U}_{SM}} \rho(x, U(\cdot)), \ x \in \mathbb{R}^d.$$

Proof. For $\varepsilon > 0$ and $\delta > 0$, define a smooth Markov control $u^{\varepsilon,\delta}$ as follows.

$$u^{\varepsilon,\delta}(x) = u^*_{\varepsilon} \star \rho_{\delta}(x), \ x \in \mathbb{R}^d$$

where u_{ε}^{*} is a stationary optimal Markov control for the problem (4.3); (2.2), ρ_{δ} is the density of $N(0, \delta)$ and \star denote convolution product. Then

(4.24)
$$\lim_{\delta \to 0} \int f(v) u^{\varepsilon,\delta}(x) (dv) = \int f(v) u^*_{\varepsilon}(x) (dv), \ f \in C(\mathbb{U}).$$

Since \mathcal{U}_{SM} is compact under the topology given in (1.5), along a subsequence $u^{\varepsilon,\delta} \to u^{\varepsilon}$ in (1.5) as $\delta \to 0$. Hence, we have for $g \in C(\mathbb{U}), f \in L^1(\mathbb{R}^d) \cap L^2(\mathbb{R}^d)$,

$$\lim_{\delta \to 0} \int_{\mathbb{R}^d} f(x) \int_{\mathbb{U}} g(v) v^{\varepsilon,\delta}(x) (dv) dx = \int_{\mathbb{R}^d} f(x) \int_{\mathbb{U}} g(v) u^{\varepsilon}(x) (dv) dx.$$

Hence we have

$$\lim_{\delta \to 0} \int_{\mathbb{U}} g(v) u^{\varepsilon,\delta}(x) (dv) = \int_{\mathbb{U}} g(v) u^{\varepsilon}(x) (dv) \text{ a.e. } x \text{ for all } g \in C(\mathbb{U}).$$

Hence $u^{\varepsilon} = u^*_{\varepsilon}$, therefore $u^{\varepsilon,\delta} \to u^*_{\varepsilon}$ in \mathcal{U}_{SM} as $\delta \to 0$.

Now for each $\varepsilon > 0$ fixed, using Lemma 3.2.6, p.89, Lemma 3.3.4, pp.97-98, [1], it follows that $\eta^{\varepsilon,\delta} \to \eta^*_{\varepsilon}$ in $\mathcal{P}(\mathbb{R}^d)$, where $\eta^{\varepsilon,\delta}, \eta^*_{\varepsilon}$ denote respectively the invariant measures of the processes (4.3) corresponding to the controls $u^{\varepsilon,\delta}$ and u^*_{ε} . Hence there exists a smooth control u^{ε} such that

(4.25)
$$|\rho_{\varepsilon}(x, u^{\varepsilon}(\cdot)) - \rho_{\varepsilon}(x, u^{*}_{\varepsilon}(\cdot))| \leq \varepsilon.$$

Let $X^{\varepsilon,\delta}(\cdot)$ denote the solution of the sde (4.3) corresponding to the smooth stationary Markov control $u^{\varepsilon,\delta}$ and $X^{\delta}(\cdot)$ denote the solution of the sde (1.1) corresponding to the control $U^{\varepsilon,\delta}(t) = u^{\varepsilon,\delta}(X^{\varepsilon,\delta}(t))$. Then we have

$$\begin{split} \frac{1}{t} E \Bigg[\int_0^t (r(X^{\varepsilon,\delta}(s), U^{\varepsilon,\delta}(s)) - r(X^{\delta}(s), U^{\varepsilon,\delta}(s))) ds \Bigg] \\ & \leq \frac{1}{t} E \Bigg[\int_0^t h_R(\|X^{\varepsilon,\delta}(s) - X^{\delta}(s)\|) ds \Bigg] \\ & + 2\|r\|_\infty \frac{1}{t} \int_0^t P(\|X^{\varepsilon,\delta}(s) - X^{\delta}(s)\| \ge R) ds \\ & := I_1(R)[u^{\varepsilon,\delta}] + I_2(R)[u^{\varepsilon,\delta}] \end{split}$$

Let $\eta_{\epsilon,i}[u]$ be a limit point of empirical probability measures of $Y_i^{\epsilon}(\cdot)$ given by (4.4) corresponding a smooth Markov control u satisfying

$$\limsup_{t \to \infty} \frac{1}{t} E\Big[\int_0^t h_R(\|Y_i^{\varepsilon}(s)\|) ds\Big] = \int h_R(\|x\|) \eta_{\epsilon,i}[u](dx),$$
$$\limsup_{t \to \infty} \frac{1}{t} \int_0^t P\big(\|Y_i^{\varepsilon}(s)\| \ge R\big) ds \le \eta_{\epsilon,i}[u](B_R^c).$$

Hence, it follows that

(4.26)
$$\limsup_{t \to \infty} I_1(R)[u] \leq \sum_{i=1}^2 \int_{\mathbb{R}^d} h_R(\|x\|) \eta_{\epsilon,i}[u](dx),$$
$$\lim_{t \to \infty} \sup_{t \to \infty} I_2(R)[u] \leq 2\|r\|_{\infty} \sum_{i=1}^2 \eta_{\epsilon,i}[u](B_R^c).$$

Therefore,

(4.27)
$$\limsup_{t \to \infty} \frac{1}{t} E \left[\int_0^t (r(X^{\varepsilon,\delta}(s), U^{\varepsilon,\delta}(s)) - r(X^{\delta}(s), U^{\varepsilon,\delta}(s))) ds \right]$$
$$\leq \sup_{u \in \mathcal{U}_{SM}^{smooth}} \sup_{\eta \in \mathcal{H}_{\varepsilon,i}[u]} \Big(\sum_{i=1}^2 \int_{\mathbb{R}^d} h_R(\|x\|) \eta(dx) + 2\|r\|_{\infty} \sum_{i=1}^2 \eta(B_R^c) \Big).$$

Using (4.27), we have

$$\begin{aligned}
\rho_{\varepsilon}^{*}(x) &- \inf_{U(\cdot) \in \mathcal{U}_{SM}} \rho(x, U(\cdot)) \geq -\varepsilon - \rho_{\varepsilon}(x, U^{\varepsilon, \varepsilon}(\cdot)) - \rho(x, U^{\varepsilon, \varepsilon}(\cdot)) \\
&\geq -\varepsilon - \limsup_{t \to \infty} I_{1}(R)[u^{\varepsilon, \varepsilon}] - \limsup_{t \to \infty} I_{2}(R)[u^{\varepsilon, \varepsilon}] \\
&\geq -\varepsilon - \sup_{u \in \mathcal{U}_{SM}^{smooth}} \sup_{\eta \in \mathcal{H}_{\varepsilon, i}[u]} \Big(\sum_{i=1}^{2} \int_{\mathbb{R}^{d}} h_{R}(||x||) \eta(dx) \\
&+ 2||r||_{\infty} \sum_{i=1}^{2} \eta(B_{R}^{c})\Big).
\end{aligned}$$

Now combining the above with Lemma 4.4 and the assumption (D), we complete the proof. $\hfill \Box$

From the above Theorem, we can deduce the following.

Theorem 4.7. Assume (A1), (B) and (D). Then there exists a sequence of ε ergodic controls $U^{\varepsilon}(\cdot)$ of for the problem(4.3);(2.2) such that

$$\lim_{\varepsilon \to 0} \rho(x, U^{\varepsilon}(\cdot)) = \inf_{u(\cdot) \in \mathcal{U}_{SM}} \rho(x, u(\cdot)), \ x \in \mathbb{R}^d.$$

Proof. Set $u^{\varepsilon}(\cdot) = u^{\varepsilon,\varepsilon}$, where $u^{\varepsilon,\varepsilon}$ as in the proof of Theorem 4.6 and $U^{\varepsilon}(t) = u^{\varepsilon}(X^{\varepsilon}(t)), t \geq 0$. Then using (4.28), we have

$$-\varepsilon - \sup_{u \in \mathcal{U}_{SM}^{smooth}} \sup_{\eta \in \mathcal{H}_{\varepsilon,i}[u]} \left(\sum_{i=1}^{2} \int_{\mathbb{R}^{d}} h_{R}(\|x\|) \eta(dx) + 2\|r\|_{\infty} \sum_{i=1}^{2} \eta(B_{R}^{c}) \right)$$

$$\leq \rho_{\varepsilon}^{*}(x) - \rho(x, U^{\varepsilon}(\cdot))$$

$$\leq \sup_{u \in \mathcal{U}_{SM}^{smooth}} \sup_{\eta \in \mathcal{H}_{\varepsilon,i}[u]} \left(\sum_{i=1}^{2} \int_{\mathbb{R}^{d}} h_{R}(\|x\|) \eta(dx) + 2\|r\|_{\infty} \sum_{i=1}^{2} \eta(B_{R}^{c}) \right).$$

The last inequality follows from (4.20). Now combining the above inequality with Theorem 4.6, we get

$$\lim_{\varepsilon \to 0} \rho(x, U^{\varepsilon}(\cdot)) = \inf_{u(\cdot) \in \mathcal{U}_{SM}} \rho(x, u(\cdot)), \ x \in \mathbb{R}^d.$$

Now we give a sufficient condition for the assumption (D).

Lemma 4.8. Assume $b_i(\cdot)$ in assumption (B) satisfies $\langle b_i(x), x \rangle < -d^2 ||x||^2, x \in \mathbb{R}^d$ and Lipschitz constant L of σ_{ij} for all i, j satisfies $d^2L^2 < 2$, then (D) holds.

Proof. Set $\hat{a} = \hat{\sigma}(0)\hat{\sigma}(0)^T$. For $u \in \mathcal{U}_{SM}$, let $Y_i^{\varepsilon}(\cdot)$ denote the solution to (4.4) corresponding to $u(X^{\varepsilon}(\cdot))$. Then using Ito's formula, we have

$$dE \|Y_i^{\varepsilon}(t)\|^2 = \left(2E \langle b_i(Y_i^{\varepsilon}(t)), Y_i^{\varepsilon}(t) \rangle + \frac{1}{2} \sum_{j,k=1}^d E(\sigma_{jk}(X^{\varepsilon}(t)) - \sigma_{jk}(X_{\varepsilon}(t)))^2 \right. \\ \left. + \varepsilon^2 \sum_{j,k=1}^d \hat{a}_{jk} \right) dt \\ \leq \left(- 2E \|Y_i^{\varepsilon}(t)\|^2 + \frac{1}{2} d^2 L^2 \|Y^{\varepsilon}(t)\|^2 + \varepsilon^2 \sum_{j,k=1}^d \hat{a}_{jk} \right) dt.$$

 Set

$$f(t) = E[||Y_1^{\varepsilon}(t)||^2 + ||Y_2^{\varepsilon}(t)||^2], t \ge 0.$$

Then we get

$$df(t) \leq (-2f(t) + d^{2}L^{2}E ||Y^{\varepsilon}(t)||^{2} + \sum_{j,k=1}^{d} \hat{a}_{jk})dt$$

$$\leq -(2 - d^{2}L^{2})f(t)dt + \sum_{j,k=1}^{d} \hat{a}_{jk}dt.$$

The second inequality follows from Theorem 4.1. Now using comparison theorem of odes, we get

(4.29)
$$E[\|Y_1^{\varepsilon}(t)\|^2 + \|Y_2^{\varepsilon}(t)\|^2] \le \frac{\varepsilon^2}{2 - d^2 L^2} \left(1 - e^{-(2 - d^2 L^2)t}\right) \sum_{j,k=1}^d \hat{a}_{jk}, t \ge 0.$$

Now using Chebychev's inequality, we get

$$P(\|Y_i^{\varepsilon}(t)\| \ge R) \le \frac{\varepsilon^2}{(2-d^2L^2)R^2} \left(1 - e^{-(2-d^2L^2)t}\right) \sum_{j,k=1}^d \hat{a}_{jk}.$$

Hence

(4.30)
$$\frac{1}{t} \int_0^t P(\|Y_i^{\varepsilon}(s)\| \ge R) ds \le \frac{\varepsilon^2}{(2-d^2L^2)R^2} \sum_{j,k=1}^d \hat{a}_{jk} := \frac{K_1 \varepsilon^2}{R^2}, t > 0.$$

From (4.30), we get for $u \in \mathcal{U}_{SM}$,

(4.31)
$$\eta(B_R^c) \le \frac{K_1 \varepsilon^2}{R^2}, \ \eta \in \mathcal{H}_{\varepsilon,i}[u].$$

Hence for $f \in C_b(\mathbb{R}^d)$,

$$\sup_{u \in \mathcal{U}_{SM}} \sup_{\eta \in \mathcal{H}_{\varepsilon,i}[u]} \int f(x)\eta(dx) = \sup_{u \in \mathcal{U}_{SM}} \sup_{\eta \in \mathcal{H}_{\varepsilon,i}[u]} \int_{\|x\| \le \sqrt{\varepsilon}} f(x)\eta(dx) + \sup_{u \in \mathcal{U}_{SM}} \sup_{\eta \in \mathcal{H}_{\varepsilon,i}[u]} \int_{\|x\| > \sqrt{\varepsilon}} f(x)\eta(dx) \leq \sup_{\|x\| \le \sqrt{\varepsilon}} |f(x)| + \|f\|_{\infty} K_{1}\varepsilon \rightarrow 0 \text{ as } \varepsilon \rightarrow 0.$$

Hence (D) follows.

Theorem 4.9. Assume (A1), (B1)(i), (C) and $\langle b_i(x), x \rangle < -d^2 ||x||^2, x \in \mathbb{R}^d$ and Lipschitz constant L of σ_{ij} for all i, j satisfies $d^2L^2 < 2$ Then

$$|\rho_{\varepsilon}^*(x) - \hat{\rho}_{\mathcal{U}_{SM}}^*(x)| \leq \hat{K}\sqrt{\varepsilon}, \ x \in \mathbb{R}^d,$$

where $\hat{K} > 0$ is some constant.

Proof. Note that given hypothesis implies (B). Hence from Lemma 4.4, and using (4.31) and (4.32), we get

$$\rho_{\varepsilon}^{*}(x) - \rho_{\mathcal{U}_{SM}}^{*}(x) \leq \sup_{u \in \mathcal{U}_{SM}} \sup_{\eta_{i} \in \mathcal{H}_{\varepsilon,i}[u]} \left(\sum_{i=1}^{2} \int_{\mathbb{R}^{d}} h_{R}(\|x\|) \eta_{i}(dx) + 2\|r\|_{\infty} \sum_{i=1}^{2} \eta_{i}(B_{R}^{c}) \right) \\
\leq 2K_{1}\varepsilon^{2} + 2 \sup_{\|x\| \leq \sqrt{\varepsilon}} h_{1}(\|x\|) + 2\|h_{1}\|_{\infty}K_{1}\varepsilon + 4\|r\|_{\infty} \frac{K_{1}\varepsilon^{2}}{R^{2}} \\
= 2\left(1 + \frac{2\|r\|_{\infty}}{R^{2}}\right)K_{1}\varepsilon^{2} + 2\operatorname{Lip}(r)\sqrt{\varepsilon} + 2\operatorname{Lip}(r)K_{1}\varepsilon.$$

From (4.25), (4.27), we get

$$\rho_{\varepsilon}^{*}(x) - \rho_{\mathcal{U}_{SM}}^{*}(x) \geq -\sup_{u \in \mathcal{U}_{SM}} \sup_{\eta_{i} \in \mathcal{H}_{\varepsilon,i}[u]} \left(\sum_{i=1}^{2} \int_{\mathbb{R}^{d}} h_{R}(\|x\|) \eta_{i}(dx) + 2\|r\|_{\infty} \sum_{i=1}^{2} \eta_{i}(B_{R}^{c}) \right) - \varepsilon \\
\geq -2\left(1 + \frac{2\|r\|_{\infty}}{R^{2}}\right) K_{1}\varepsilon^{2} - 2\operatorname{Lip}(r)\sqrt{\varepsilon} - 2\operatorname{Lip}(r)K_{1}\varepsilon - \varepsilon.$$

Combining the above two inequalities, the result follows.

Remark 4.10. Neither Theorem 4.6 nor Theorem 4.7 implies that $\rho_{\mathcal{U}}^*(x) = \rho_{\mathcal{U}_{SM}}^*(x)$ for all $x \in \mathbb{R}^d$. But from Theorem 2.3, it follows that $\rho(x, U^*(\cdot)) = \rho_{\mathcal{U}}^*(x)$ for all $x \in \operatorname{supp}(\eta^*)$.

i.e., $U^*(\cdot)$ is ergodic optimal for all initial conditions $x \in \text{supp}(\eta^*)$, in the sense of Definition 1.1(i).

4.1. Constant Diffusion matrix. We consider the case when σ is a constant non negative definite matrix. Set $\hat{\sigma}(0) = \hat{\sigma}$. The sdes (4.3), (4.4) and (4.14) respectively takes the forms

(4.33)
$$dX^{\varepsilon}(t) = m(X^{\varepsilon}(t), U(t))dt + (\sigma + \varepsilon\hat{\sigma})dW(t),$$

(4.34)
$$dY_i^{\varepsilon}(t) = b_i(Y_i^{\varepsilon}(t))dt + \varepsilon \hat{\sigma} dW(t),$$

(4.35)
$$dY^{\varepsilon}(t) = (m(X^{\varepsilon}(t), U(t)) - m(X(t), U(t)))dt + \varepsilon \,\hat{\sigma} dW(t).$$

Let $V_i(0, x)$ denote the quasi potential given by

$$V_i(0,x) = \inf \left\{ \frac{1}{2} \int_0^T \langle (\dot{\varphi}(t) - b_i(\varphi(t)), \hat{a}(\varphi(t))(\dot{\varphi}(t) - b_i(\varphi(t))) \rangle dt : \varphi \in C[0, T], \varphi(0) = 0, \varphi(T) = x, T > 0 \right\}$$
$$= \inf_{u(\cdot) \in \mathcal{U}_i} \int_0^\infty u(t)^T \hat{a}^{-1} u(t) dt$$

where $\hat{a} = \hat{\sigma}\hat{\sigma}^T$ and \mathcal{U}_i is the set of all measurable $u : [0, \infty) \to \mathbb{R}^d$ such that the solution $y_i(\cdot)$ of

$$dy_i(t) = -(b_i(y_i(t)) + u(t))dt, y(0) = x$$

satisfies $y_i(t) \to 0$ as $t \to \infty$.

Under (B), the sde (4.34) has a unique invariant probability distribution. Since the process $Y_i^{\varepsilon}(\cdot)$ is Feller, it follows that any limit point $\eta_{\varepsilon,i}$ of empirical measures given in Lemma 4.2 is an invariant distribution, see for example Theorem 1.5.15, p.22, [1], and hence empirical measures converges to its unique invariant probability distribution $\eta_{\varepsilon,i}$. Therefore from Lemma 4.2, we have $\eta_{\varepsilon,i} \to \delta_0$ weakly.

We use the following large deviations result about the invariant probability measures of (4.34).

Lemma 4.11. Assume (C). The process $Y_i^{\varepsilon}(\cdot)$ given by (4.34) has a unique invariant probability measure $\eta_{\varepsilon,i}$ has a density $\varphi_{\varepsilon,i}$ and satisfies (i)

$$\lim_{\varepsilon \to 0} \varepsilon^2 \ln \eta_{\varepsilon,i}(D) = -\inf_{x \in D} V_i(0,x), \ i = 1, 2,$$

for any domain $D \subseteq \mathbb{R}^d$.

SURESH AND VIKRANT

(ii)

24

$$\lim_{\varepsilon \to 0} \varepsilon^2 \ln \varphi_{\varepsilon,i}(x) = -V_i(0,x), x \in \mathbb{R}^d.$$

Proof. The first part follows easily by mimicking the arguments of Theorem 4.3, pp.111-113, [9]. The second part follows from Theorem 2, [2].

Theorem 4.12. Assume (A1), (B) and (C) and that σ is a constant non negative definite matrix.

(i) The following inequality holds:

$$|\rho_{\epsilon}^{*}(x) - \rho_{\mathcal{U}}^{*}(x)| \leq 2 \int_{\mathbb{R}^{d}} h_{1}(||x||) e^{-\sum_{i=1}^{2} \frac{V_{i}(0,x)}{\varepsilon^{2}}} dx + 4||r||_{\infty} \sum_{i=1}^{2} e^{-\frac{\inf_{||x|| \geq 1} V_{i}(0,x)}{\varepsilon^{2}}}.$$

(ii) $\rho^*_{\mathcal{U}_{SM}}(x) = \rho^*_{\mathcal{U}}(x)$ for all $x \in \mathbb{R}^d$. (iii) If $U^*_{\varepsilon}(\cdot)$ denote the ergodic optimal control of (4.33);(2.2), then

$$\lim_{\varepsilon \to 0} \rho(x, U_{\varepsilon}^{*}(\cdot)) = \rho_{\mathcal{U}}^{*}(x), x \in \mathbb{R}^{d},$$
$$\lim_{\varepsilon \to 0} \rho_{\varepsilon}(x, U_{\varepsilon}^{*}(\cdot)) = \rho^{*}.$$

Proof. For $x \in \mathbb{R}^d$, an admissible pair $(X(\cdot), U(\cdot))$ of the sde (1.1) such that X(0) = x, we can assume without any loss of generality that $U(\cdot)$ is in prescribed form. Let $X^{\varepsilon}(\cdot)$ respectively denote solutions to (1.1) corresponding to the control $U(\cdot)$ and initial condition x. Then

$$\begin{split} \rho_{\varepsilon}^{*}(x) - \rho(x, U(\cdot)) &\leq \rho_{\varepsilon}(x, U(\cdot) - \rho(x, U(\cdot))) \\ &\leq \limsup_{t \to \infty} \frac{1}{t} E \Biggl[\int_{0}^{t} (r(X^{\epsilon}(s), U(s)) - r(X(s), U(s))) ds \Biggr] \\ &\leq \limsup_{t \to \infty} \frac{1}{t} E \Biggl[\int_{0}^{t} h_{R}(\|X^{\epsilon}(s) - X(s)\|) ds \Biggr] \\ &+ 2\|r\|_{\infty} \limsup_{t \to \infty} \frac{1}{t} \int_{0}^{t} P(\|X^{\epsilon}(s) - X(s)\| \ge R) ds. \end{split}$$

Now using the same argument as in the proof of Lemma 4.4, we have

$$\rho_{\epsilon}^{*}(x) - \rho_{\mathcal{U}}^{*}(x) \leq \sum_{i=1}^{2} \int_{\mathbb{R}^{d}} h_{1}(\|x\|) \eta_{\epsilon,i}(dx) + 2\|r\|_{\infty} \sum_{i=1}^{2} \eta_{\epsilon,i}(B_{1}^{c}),$$

where $\eta_{\epsilon,i}(dx)$ is the unique invariant probability measure of $Y_i^{\varepsilon}(\cdot)$. Now repeat the argument with $U^{\varepsilon}(t) = u_{\varepsilon}^*(X^{\varepsilon}(t)), t \ge 0$, where u_{ε}^* is an ergodic optimal stationary Markov control of (4.33);(2.2), we get

$$\rho_{\epsilon}^{*}(x) - \rho_{\mathcal{U}}^{*}(x) \ge -\Big(\sum_{i=1}^{2} \int_{\mathbb{R}^{d}} h_{1}(\|x\|)\eta_{\epsilon,i}(dx) + 2\|r\|_{\infty} \sum_{i=1}^{2} \eta_{\epsilon,i}(B_{1}^{c})\Big).$$

Thus we have

(4.36)
$$|\rho_{\epsilon}^{*}(x) - \rho_{\mathcal{U}}^{*}(x)| \leq \sum_{i=1}^{2} \int_{\mathbb{R}^{d}} h_{1}(||x||) \eta_{\epsilon,i}(dx) + 2||r||_{\infty} \sum_{i=1}^{2} \eta_{\epsilon,i}(B_{1}^{c}).$$

From Lemma 4.11 (i), we get for small enough ε

(4.37)
$$0 \le \eta_{\varepsilon,i}(B_1^c) \le 2e^{-\frac{\inf \|x\| \ge 1}{\varepsilon^2} V_i(0,x)}, \ i = 1, 2.$$

From Lemma 4.11 (ii), we get for small enough ε

(4.38)
$$0 \le \int_{\mathbb{R}^d} h_1(\|x\|) \eta_{\varepsilon,i}(dx) \le 2 \int_{\mathbb{R}^d} h_1(\|x\|) e^{-\frac{V_i(0,x)}{\varepsilon^2}} dx, \ i = 1, 2.$$

Now combining (4.36), (4.37) and (4.38), we get the desired bounds(i). Now proof of (ii) is easy and the proof of second limit in (iii) follows from Theorem 2.3.

5. Tunneling of controlled gradient flows in $\mathbb R$

The assumption (B) in Section 4, implicitly enforces that $m(\cdot, \cdot)$ can not have multiple local extrema for any control strategy. Hence it is not suprising to see that $\rho_{\varepsilon}(x, U^{\varepsilon}(\cdot)) \rightarrow \rho_{\mathcal{U}}^{*}(x)$ for each $x \in \mathbb{R}^{d}$. This will not be the case in general which is the subject matter of this section. In this section, we establish tunneling for the state dynamics under optimal stationary Markov control when the controlled dynamics is given by deterministic gradient flow in \mathbb{R} with an additive control taking values in \mathbb{U} which is a closed and bounded interval.

Let $V:\mathbb{R}\to\mathbb{R}$ be a smooth function with finitely many points of extrema and satisfies the growth condition

$$\lim_{|x| \to \infty} \frac{V(x)}{|x|^{1+\beta}} = \infty,$$

for some $\beta > 0$.

We consider ergodic control problem with state dynamics

(5.1)
$$dX(t) = (-V'(X(t)) + U(t))dt$$

and cost criterion

(5.2)
$$\rho(x, U(\cdot)) = \liminf_{t \to \infty} \frac{1}{t} E_x \left[\int_0^t r(X(s), U(s)) ds \right]$$

where $U(\cdot) \in \mathcal{U}$ and $X(\cdot)$ is the solution to (5.1) with initial condition X(0) = x. The corresponding small noise perturbed ergodic optimal control problem is given with state dynamics

(5.3)
$$dX^{\varepsilon}(t) = \left(-V'(X^{\varepsilon}(t)) + U(t)\right)dt + \varepsilon dW(t)$$

and cost criterion

(5.4)
$$\rho_{\varepsilon}(x, U(\cdot)) = \liminf_{t \to \infty} \frac{1}{t} E_x \left[\int_0^t r(X^{\varepsilon}(s), U(s)) ds \right]$$

where $U(\cdot) \in \mathcal{U}$ and $X^{\varepsilon}(\cdot)$ is the solution to (5.3) with initial condition x.

Let $u^{\varepsilon}(\cdot)$ be an optimal stationary Markov control for (5.3); (5.4). We make the following assumption about $u^{\varepsilon}(\cdot)$.

We assume:

Assumption (T). (i) The potential V_{ε} given by

(5.5)
$$V_{\varepsilon}(x) = V(x) - \int_0^x u^{\varepsilon}(y) dy, x \in \mathbb{R}$$

has finitely many critical points .

(ii) Along a subsequence u^{ε} converges pointwise and we denote its limit point by u^{0} .

(iii) The potential V_0 given by

(5.6)
$$V_0(x) = V(x) - \int_0^x u^0(y) dy, x \in \mathbb{R}$$

has finitely many critical points.

(iv) There exists δ -ergodic optimal u^{δ} for (5.1); (5.2), which is smooth and $u^{\delta} \rightarrow u^{0}$ pointwise.

(v) u^{ε} is piecewise smooth and $(u^{\varepsilon})'_{+}$ is uniformly bounded on compact sets.

For the remaining analysis, we take the subsequence as ε itself. Observe that $V_{\varepsilon} \to V_0$ uniformly on compact sets and hence any extremum of V_{ε} converges to the corresponding local extremum of V_0 . Hence without any loss of generality, we assume that V_{ε}, V_0 have the same set of local extrema given by $x_1 < y_1 < x_2 < \cdots < y_{N-1} < x_N$ where y_i 's are local maxima and x_i 's represent local minima. Set

$$E_1 = (-\infty, y_1), E_N = (y_{N-1}, \infty), E_i = (y_{i-1}, y_i), i = 2, \cdots, N-1.$$

For $\delta > 0$, set

(5.7)
$$u_{\delta}^{\varepsilon}(x) = \frac{1}{\delta} \int_{x}^{x+\delta} u^{\varepsilon}(y) dy, \ u_{\delta}^{0}(x) = \frac{1}{\delta} \int_{x}^{x+\delta} u^{0}(y) dy$$

Using the arguments for the proof of (4.25) in Theorem 4.6, we have

(5.8)
$$\rho_{\varepsilon}(x, u^{\varepsilon}(\cdot)) = \rho_{\varepsilon}(x, u^{\varepsilon}(\cdot)) + O(\delta).$$

We will use the following facts. For a piecewise smooth function $f : \mathbb{R} \to \mathbb{R}$,

• If f is right continuous, then f_{δ} is differentiable and

$$f'_{\delta}(x) = \frac{1}{\delta}(f(x+\delta+) - f(x+)),$$

where f(x+) denote the right limit of f at x.

• More over

$$\lim_{\delta \to 0} f'_{\delta}(x) = f'_{+}(x),$$

where $f'_{+}(x)$ denote the right derivative of f at x.

Define the potentials

(5.9)
$$V_{\varepsilon,\delta}(x) = V(x) - \int_0^x u_{\delta}^{\varepsilon}(y) dy,$$
$$V_{0,\delta}(x) = V(x) - \int_0^x u_{\delta}^0(y) dy, x \in \mathbb{R}$$

It is easy to see that for $\delta > 0$ small enough, set of local extrema of $V_{\varepsilon,\delta}, V_{0,\delta}$ is $\{x_1, y_1, \dots, y_{N-1}, x_N\}$. Also using assumption (T), it follows that

(5.10) $|V_{\varepsilon,\delta}(x) - V_{\varepsilon}(x)| \leq K_1(a,b)\delta, \ x \in [a, b],$

(5.11)
$$|V_{\varepsilon,\delta}(x) - V_{0,\delta}(x)| \leq \omega_{a,b}(\varepsilon), \ x \in [a, b],$$

(5.12)
$$\lim_{\varepsilon \to 0} V_{\varepsilon,\delta}''(x) = V_{0,\delta}''(x), x \in \mathbb{R},$$

where $K_1(a, b)$ is a constant depends only on a, b and $\omega_{a,b}$ is a modulus of continuity. Set

(5.13)
$$\overline{V}_{\varepsilon,\delta}(y_j) = V_{\varepsilon,\delta}(y_j) - V_{\varepsilon,\delta}(x_i), \ j = i - 1, i, \varepsilon \ge 0.$$

Consider the ode

(5.14)
$$dX(t) = -V'_{0,\delta}(X(t))dt$$

and the small noise perturbed sdes given by

(5.15)
$$dX_{\delta}^{\varepsilon}(t) = -V_{\varepsilon,\delta}'(X_{\delta}^{\varepsilon}(t))dt + \varepsilon dW(t)$$

and

(5.16)
$$dX^{\varepsilon}(t) = -V'_{\varepsilon}(X^{\varepsilon}(t))dt + \varepsilon dW(t),$$

where $W(\cdot)$ is a $\{\mathcal{F}_t\}$ -Wiener process in \mathbb{R} . Define the stoping times $\tau_i^{\varepsilon,\delta}, \tau_i^{\varepsilon}, i = 1, 2, \cdots, N$ as

(5.17)
$$\tau_i^{\varepsilon,\delta} = \inf\{t \ge 0 | X_{\delta}^{\varepsilon}(t) \notin E_i\},$$

(5.18)
$$\tau_i^{\varepsilon} = \inf\{t \ge 0 | X^{\varepsilon}(t) \notin E_i\}$$

Lemma 5.1. For each $\delta > 0$, follow holds.

$$\lim_{\varepsilon \to 0} \varepsilon^2 \ln E_x \tau_i^{\varepsilon, \delta} = \min\{ \overline{V}_{0,\delta}(y_{i-1}), \overline{V}_{0,\delta}(y_i) \} := 2\lambda_i^{\delta}, x \in E_i, i = 1, 2, \cdots, N.$$

Proof. Observe that $V'_{\varepsilon,\delta} \to V'_{0,\delta}$ uniformly on compact subsets and $V''_{\varepsilon,\delta} \to V''_{0,\delta}$ pointwise. By closely mimicking the arguments in the proof of Theorem 4.1, pp.106-109 of [9], it follows that

$$\lim_{\varepsilon \to 0} \left(\varepsilon^2 \ln E_x \tau_i^{\varepsilon, \delta} - \min\{ \bar{V}_{\varepsilon, \delta}(y_{i-1}), \bar{V}_{\varepsilon, \delta}(y_i) \} \right) = 0.$$

Hence the result follows.

Let

$$S = \operatorname{argmax}_{i} \lambda_{i}^{\delta} := \{x_{m_{1}}, x_{m_{2}}, \cdots, x_{m_{\kappa}}\}, x_{m_{1}} < x_{m_{2}} < \cdots < x_{m_{\kappa}},$$

$$(5.19) \qquad \lambda^{\delta} = \max_{i} \lambda_{i}^{\delta},$$

$$W_{1} = (-\infty, y_{m_{1}}), W_{\kappa} = (y_{m_{\kappa-1}}, \infty),$$

$$W_{i} = (y_{m_{i-1}}, y_{m_{i}}), i = 2, \cdots, \kappa$$

denote the deep wells and their respective local minima. Define $\hat{X}_{\delta}^{\varepsilon}(t) = X_{\delta}^{\varepsilon}(e^{\frac{2}{\varepsilon^2}\lambda^{\delta}}t), t \geq 0$. Let $(y_i^1, y_i^2) = V_i \subset V_i' \subset W_i, i = 1, 2, \cdots, \kappa$ be such that $x_{m_i} \in V_i$ for all i and V_i' is a distance r > 0 from the boundary ∂W_i . Set $V = \bigcup_{i=1}^{\kappa} V_i$. Define the trace of $\hat{X}_{\delta}^{\varepsilon}(\cdot)$ as follows.

(5.20)
$$Y_{\delta}^{\varepsilon}(t) = \hat{X}_{\delta}^{\varepsilon}(S^{\varepsilon,\delta}(t)), t \ge 0, \text{ where}$$
$$T^{\varepsilon,\delta}(t) = \int_{0}^{t} I_{\{\hat{X}_{\delta}^{\varepsilon}(s)\in V\}} ds, t \ge 0,$$
$$S^{\varepsilon,\delta}(t) = \sup\{s \ge 0 : T^{\varepsilon,\delta}(s) \le t\}, t \ge 0.$$

It is easy to see that for each $t, S^{\varepsilon,\delta}(t)$ is a $\{\mathcal{F}_t\}$ - stopping time. Set $\mathcal{G}_t = \mathcal{F}_{S(t)}, t \ge 0$.

Let $\Psi : \mathbb{R} \setminus \{y_{m_1}, \cdots, y_{m_\kappa}\} \to S$ be defined as

$$\Psi(x) = x_{m_i}, \text{ if } x \in W_i, i = 1, 2, \cdots, \kappa.$$

Consider the process

$$Z^{\varepsilon}_{\delta}(t) = \Psi(Y^{\varepsilon}_{\delta}(t)), t \ge 0.$$

To characterize the limit of $Z^{\varepsilon}_{\delta}(\cdot)$, we need some auxillary results. Set

(5.21)
$$C_{\delta} = \sum_{j=1}^{\kappa} \frac{1}{\sqrt{|V_{0,\delta}''(x_{m_j})|}}$$

Lemma 5.2. Follwing estimates holds.

(i)

$$\int_{\mathbb{R}} e^{-\frac{2}{\varepsilon^2} V_{\varepsilon,\delta}(x)} dx = \sqrt{\pi} \varepsilon e^{-\frac{2}{\varepsilon^2} \lambda^{\delta}} C_{\delta}(1+O(\varepsilon))$$

(ii) Let $\eta^{\varepsilon,\delta}$ denote the invariant distribution of (5.15). Then

(5.22)
$$\eta^{\varepsilon,\delta}(V_i) = \frac{1}{C_{\delta}\sqrt{|V_{0,\delta}'(x_{m_i})|}} (1+O(\varepsilon)), i = 1, 2, \cdots, \kappa.$$

Proof. Applying Laplace method, we get

$$\begin{split} \int_{\mathbb{R}} e^{-\frac{2}{\varepsilon^2} V_{\varepsilon,\delta}(x)} dx &= \sqrt{\pi} \varepsilon e^{-\frac{2}{\varepsilon^2} \lambda^{\delta}} \sum_{j=1}^{\kappa} \frac{1}{\sqrt{|V_{\varepsilon,\delta}''(x_{m_j})|}} (1+O(\varepsilon)) \\ &= \sqrt{\pi} \varepsilon e^{-\frac{2}{\varepsilon^2} \lambda^{\delta}} \sum_{j=1}^{\kappa} \frac{1}{\sqrt{|V_{0,\delta}''(x_{m_j})|}} (1+O(\varepsilon)). \end{split}$$

The last equality follows from (5.12). This completes the proof of (i) .

A similar application of Laplace method to the interval V_i yields (ii).

Let $\hat{\tau}_i^{\varepsilon,\delta}$ denote the exit time of the process $X_{\delta}^{\varepsilon}(\cdot)$ from $W_i, i = 1, 2, \cdots, \kappa$. Set

$$P_{x_{m_{i}}}(X_{\delta}^{\varepsilon}(\hat{\tau}_{i}^{\varepsilon,0}) = y_{m_{i}}) = p_{ii+1}^{\varepsilon,0},$$

$$P_{x_{m_{i}}}(X_{\delta}^{\varepsilon}(\hat{\tau}_{i}^{\varepsilon,0}) = y_{m_{i-1}}) = p_{ii-1}^{\varepsilon,0},$$

$$p_{ii+1}^{\delta} = \frac{\sqrt{|V_{0,\delta}''(y_{m_{i-1}})|}}{\sqrt{|V_{0,\delta}''(y_{m_{i-1}})|} + \sqrt{|V_{0,\delta}''(y_{m_{i}})|}},$$

$$p_{ii-1}^{\delta} = \frac{\sqrt{|V_{0,\delta}''(y_{m_{i-1}})|} + \sqrt{|V_{0,\delta}''(y_{m_{i}})|}}{\sqrt{|V_{0,\delta}''(y_{m_{i-1}})|} + \sqrt{|V_{0,\delta}''(y_{m_{i}})|}}.$$

Since $\psi(x) = P_x \left(X_{\delta}^{\varepsilon}(\hat{\tau}_i^{\varepsilon,\delta}) = y_{m_i} \right), x \in W_i$ uniquely solve

(5.24)
$$L^{\varepsilon,\delta}\psi := \frac{\varepsilon^2}{2}\psi'' - V'_{\varepsilon,\delta}\psi' = 0, \ \psi(y_{m_{i-1}}) = 0, \ \psi(y_{m_i}) = 1.$$

Hence, we get

$$p_{ii+1}^{\varepsilon,\delta} = \frac{\int_{y_{m_{i-1}}}^{x_{m_i}} e^{\frac{2}{\varepsilon^2} V_{\varepsilon,\delta}(x)} dx}{\int_{y_{m_{i-1}}}^{y_{m_i}} e^{\frac{2}{\varepsilon^2} V_{\varepsilon,\delta}(x)} dx}.$$

Now repeating similar computions as in the proof of Lemma 5.2, we have the following.

Lemma 5.3. Follwing estimates hold.

$$\begin{array}{lll} p_{ii+1}^{\varepsilon,\delta} &=& p_{ii+1}^{\delta} + O(\varepsilon), \\ p_{ii-1}^{\varepsilon,\delta} &=& p_{ii-1}^{\delta} + O(\varepsilon). \end{array}$$

 Set

$$\mu^{\delta}(x_{m_{i}}) = \frac{1}{C_{\delta}\sqrt{|V_{0,\delta}'(x_{m_{i}})|}},$$

$$\lambda(1) = \frac{1}{C_{\delta}\mu^{\delta}(x_{m_{1}})\sqrt{|V_{0,\delta}''(y_{m_{1}})|}}$$

$$(5.25) \qquad \lambda(i) = \frac{1}{C_{\delta}\mu^{\delta}(x_{m_{i}})} \left(\frac{1}{\sqrt{|V_{0,\delta}'(y_{m_{i-1}})|}} + \frac{1}{\sqrt{|V_{0,\delta}''(y_{m_{i}})|}}\right), i \ge 2,$$

$$Q^{\delta}(x_{m_{i}}, x_{m_{i+1}}) = \frac{1}{Z^{\delta}\mu^{\delta}(x_{m_{i}})\sqrt{|V_{0,\delta}''(y_{m_{i-1}})|}}, i = 1, 2, \cdots, \kappa - 1,$$

$$Q^{\delta}(x_{m_{i}}, x_{m_{i-1}}) = \frac{1}{Z^{\delta}\mu^{\delta}(x_{m_{i}})\sqrt{|V_{0,\delta}''(y_{m_{i-1}})|}}, i = 2, \cdots, \kappa.$$

Let $Z_{\delta}(\cdot)$ denote the continuous time Markov chain with state space S with rate matrix Q^{δ} . Then its generator is given by, for $i = 1, 2, \cdots, \kappa$,

$$(5.26) \ L^{\delta}f(x_{m_i}) = \lambda(i)p_{ii-1}^{\delta}\big(f(x_{m_i}) - f(x_{m_{i-1}})\big) + \lambda(i)p_{ii+1}^{\delta}\big(f(x_{m_i}) - f(x_{m_{i+1}})\big).$$

Let $h_i : \mathbb{R} \to [0, 1]$ be a smooth function such that $h_i(x) = 1, x \in V_i, h_i(x) = 0, x \in \mathbb{R} \setminus V'_i, i = 1, 2, \cdots, \kappa$.

Lemma 5.4. For $F: S \to \mathbb{R}$, the ode

(5.27)
$$e^{\frac{2}{\varepsilon^2}\lambda^{\delta}}L^{\varepsilon,\delta}f_{\varepsilon} = -\sum_{i=1}^{\kappa}L^{\delta}F(x_{m_i})h_i$$

has a solution $f_{\varepsilon} \in W^{2,p}(\mathbb{R}), p \geq 2$ such that $f_{\varepsilon}(x) \to F(x_{m_i}), x \in V_i, i = 1, 2, \cdots, \kappa$.

Proof. Let $V_i = (y_i^1, y_i^2), i = 1, 2, \cdots, \kappa$. Let $(a(i), b(i)), i = 1, 2, \cdots, \kappa$ are chosen such that

$$F(x_{m_1}) = LF(x_{m_1}) + b(1)p_{12}^{\delta}$$

(5.28)
$$F(x_{m_i}) = LF(x_{m_i}) + a(i)p_{ii-1}^{\delta} + b(i)p_{ii+1}^{\delta}, i = 2, \cdots, \kappa - 1,$$

$$F(x_{m_{\kappa}}) = LF(x_{m_{\kappa}}) + a(\kappa)p_{\kappa\kappa-1}^{\delta}.$$

Observe that the choice is not unique. Set $a(1) = b(\kappa) = 0$. Consider the ode

(5.29)
$$L^{\varepsilon,\delta}f = -e^{-\frac{2}{\varepsilon^2}\lambda^{\delta}}L^{\delta}F(x_{m_i}), \ x \in V_i, f(y_i^1) = a(i), f(y_i^2) = b(i), \ i = 1, 2, \cdots, \kappa.$$

Let $\tilde{\tau}_i^{\varepsilon,\delta}$ denote the exit time of $X_{\delta}^{\varepsilon}(\cdot)$ from $V_i, i = 1, 2, \cdots, \kappa$. Then it is easy to see that solution $f_{\varepsilon}^i \in C^2(V_i)$, of (5.29) satisfies

$$\begin{split} f_{\varepsilon}^{1}(x) &= e^{-\frac{2}{\varepsilon^{2}}\lambda^{\delta}}LF(x_{m_{1}})E_{x}[\tilde{\tau}_{1}^{\varepsilon,\delta}] + b(1)p_{12}^{\delta} + O(\varepsilon), x \in V_{1} \\ f_{\varepsilon}^{i}(x) &= e^{-\frac{2}{\varepsilon^{2}}\lambda^{\delta}}LF(x_{m_{i}})E_{x}[\tilde{\tau}_{i}^{\varepsilon,\delta}] + a(i)p_{ii-1}^{\delta} + b(i)p_{ii+1}^{\delta} + O(\varepsilon), x \in V_{i}, \\ &i = 2, \cdots, \kappa - 1, \\ f_{\varepsilon}^{\kappa}(x) &= e^{-\frac{2}{\varepsilon^{2}}\lambda^{\delta}}LF(x_{m_{\kappa}})E_{x}[\tilde{\tau}_{1}^{\varepsilon,\delta}] + a(\kappa)p_{\kappa\kappa-1}^{\delta} + O(\varepsilon), x \in V_{\kappa}. \end{split}$$

Consider the ode

(5.30)
$$L^{\varepsilon,\delta}g = -e^{-\frac{2}{\varepsilon^2}\lambda^{\delta}} L^{\delta}F(x_{m_i})h_i, \ x \in W_i \setminus V_i$$
$$g(y_i^2) = f^i_{\varepsilon}(y_i^2), g(y_i^1) = f^i_{\varepsilon}(y_i^2),$$
$$g(y) = W_i \setminus V'_i, \ i = 1, 2, \cdots, \kappa.$$

Then there exists unique solution $g_{\varepsilon}^i \in C^2(W_i \setminus V_i)$ to (5.30). Then

$$f_{\varepsilon} = \sum_{i=1}^{\kappa} \left(f_{\varepsilon}^{i} I_{V_{i}} + g_{\varepsilon}^{i} I_{W_{i} \setminus V_{i}} \right).$$

is a weak solution to (5.27) in $W^{1,p}(\mathbb{R}), p \geq 2$. A straightforward regularity argument implies that $f_{\varepsilon} \in W^{2,p}(\mathbb{R}), p \geq 2$ and hence an a.e. solution as well. From Lemma 5.1 and the definition of λ^{δ} , we have

$$\lim_{\varepsilon \to 0} \varepsilon^2 \ln E_x \tilde{\tau}_i^{\varepsilon, \delta} = \lambda^{\delta}$$

Hence $f_{\varepsilon}(x) \to \sum_{i=1}^{\kappa} F(x_{m_i}), x \in V_i$ pointwise.

Now by mimicking the arguments from [16], we have the following result.

Lemma 5.5. (i) For each t > 0,

$$\lim_{\varepsilon \to 0} \sup_{x \in V_i} P_x \left(\ \breve{\tau}_i^{\varepsilon, \delta} \le t \right) \le K_1 t,$$

for some $K_1 > 0$, where $\check{\tau}_i^{\varepsilon,\delta}$ denote the exit time for $\hat{X}_{\delta}^{\varepsilon}(\cdot)$ from W_i . (ii) For $x \in V$,

$$\lim_{\varepsilon \to 0} E_x \left[\int_0^t I_{\{\hat{X}^{\varepsilon}_{\delta}(s) \in V^c\}} ds \right] = 0, \, t > 0.$$

Following the arguments of [16], using Lemma 5.5, we have

Lemma 5.6. For each $\delta > 0$, the laws of the process $Z^{\varepsilon}_{\delta}(\cdot)$ is tight.

Theorem 5.7. For each $\delta > 0$, the process $Z^{\varepsilon}_{\delta}(\cdot)$ converges in law to the continuous time Markov chain $Z_{\delta}(\cdot)$ as $\varepsilon \to 0$.

Proof. Consider the process $Z^{\varepsilon}_{\delta}(\cdot)$. Let $Z(\cdot)$ be a limit point, we take $\varepsilon \to 0$ as the corresponding subsequential limit for simplicity. Set

$$g = \sum_{i=1}^{\kappa} L^{\delta} F(x_{m_i}) h_i.$$

30

Consider the martingale

$$\begin{split} M^{\varepsilon}_{\delta}(t) &= f_{\varepsilon}(\hat{X}^{\varepsilon}_{\delta}(t)) - \int_{0}^{t} \hat{L}^{\varepsilon,\delta} f_{\varepsilon}(\hat{X}^{\varepsilon}_{\delta}(s)) ds \\ &= f_{\varepsilon}(\hat{X}^{\varepsilon}_{\delta}(t)) - \int_{0}^{t} g(\hat{X}^{\varepsilon}_{\delta}(s)) ds \\ &= f_{\varepsilon}(\hat{X}^{\varepsilon}_{\delta}(t)) - \int_{0}^{t} g(\hat{X}^{\varepsilon}_{\delta}(s)) I_{\{\hat{X}^{\varepsilon}_{\delta}(s) \in V\}} ds + \int_{0}^{t} g(\hat{X}^{\varepsilon}_{\delta}(s)) I_{\{\hat{X}^{\varepsilon}_{\delta}(s) \in V^{c}\}} ds. \end{split}$$

Since $S^{\varepsilon,\delta}(t)$ is a stopping time with respect to $\{\mathcal{F}_t\}$, it follows that

$$\hat{M}^{\varepsilon}_{\delta}(t) = M^{\varepsilon}_{\delta}(S^{\varepsilon,\delta}(t)), t \ge 0$$

is a $\{\mathcal{G}_t\}$ -martingale. Now from the definition of $S^{\varepsilon,\delta}(\cdot)$ and h_i , it follows that

$$\hat{M}^{\varepsilon}_{\delta}(t) = f_{\varepsilon}(Z^{\varepsilon}_{\delta}(t)) - \sum_{i=1}^{\kappa} \int_{0}^{t} L^{\delta}F(x_{m_{i}})I_{V_{i}}(Z^{\varepsilon}_{\delta}(s))ds + O(\varepsilon).$$

For $0 \le t_1 < t_2 \dots < t_n \le s < t, n \ge 1, \varphi \in C_b(\mathbb{R}^n)$, we have

$$E\left[\varphi(Z_{\delta}^{\varepsilon}(t_1), Z_{\delta}^{\varepsilon}(t_2), \cdots, Z_{\delta}^{\varepsilon}(t_n))(\hat{M}_{\delta}^{\varepsilon}(t) - \hat{M}_{\delta}^{\varepsilon}(s))\right] = 0$$

Now by letting $\varepsilon \to 0$, using Lemma 5.4, we get

$$E\left[\varphi(Z(t_1), Z(t_2), \cdots, Z(t_n))(\hat{M}(t) - \hat{M}(s))\right] = 0,$$

where

$$\hat{M}(t) = F(Z(t)) - \int_0^t L^{\delta} F(Z(s)) ds, t \ge 0.$$

Therefore $\hat{M}(\cdot)$ is a martigale. Hence $Z(\cdot)$ is a continuous time Markov chain with generator L^{δ} . This completes the proof.

Let $Z(\cdot)$ denote the continuous time Markov chain with state space S and generator L given by

(5.31) $Lf(x_{m_i}) = \lambda(i)p_{ii-1}(f(x_{m_i}) - f(x_{m_{i-1}})) + \lambda(i)p_{ii+1}(f(x_{m_i}) - f(x_{m_{i+1}})),$ where

$$p_{ii+1} = \frac{\sqrt{|V_0''(y_{m_{i-1}}+)|}}{\sqrt{|V_0''(y_{m_{i-1}}+)|} + \sqrt{|V_0''(y_{m_{i}}+)|}}}{p_{ii-1}} = \frac{\sqrt{|V_0''(y_{m_{i-1}}+)|}}{\sqrt{|V_0''(y_{m_{i-1}}+)|} + \sqrt{|V_0''(y_{m_{i}}+)|}}},$$

$$C_0 = \sum_{j=1}^{\kappa} \frac{1}{\sqrt{|V_0''(x_{m_{j}}+)|}}}{\sqrt{|V_0''(x_{m_{j}}+)|}},$$

$$(5.32) \quad \mu(x_{m_i}) = \frac{1}{C_0\sqrt{|V_0''(x_{m_{i}}+)|}},$$

$$\lambda(1) = \frac{1}{C_0\mu(x_{m_1})\sqrt{|V_0''(y_{m_{i-1}}+)|}} + \frac{1}{\sqrt{|V_0''(y_{m_{i}}+)|}}), i \ge 2.$$

Lemma 5.8. The invariant distribution $\eta^{\varepsilon,\delta}$ converges to the unique invariant distribution of $Z(\cdot)$ as $\varepsilon \to 0, \delta \to 0$ in that order.

Proof. This follows from Lemma 5.2 (i) and the observation that μ^{δ} given in (5.25) is the unique invariant distribution of $Z^{\delta}(\cdot)$. Now from (5.31), it follows that $\mu^{\delta} \to \mu$, the unique invariant measure of $Z(\cdot)$.

Lemma 5.9. Assume (T). Then assumption (H2) holds for u^0 .

Proof. Let $u^{\delta}(\cdot)$ be a δ -optimal smooth stationary Markov control for (5.1); (5.2), i.e., there exists $\pi^{\delta} \in \mathcal{G}$ such that

(5.33)
$$\iint \bar{r}(x,u)\pi^{\delta}(dxdu) \leq \rho^* + \delta,$$
$$\iint f(x,u)\pi^{\delta}(dxdu) = \int f(x,u^{\delta}(x))\eta^{\delta}(dx),$$

for some $\eta^{\delta} \in \mathcal{P}(\mathbb{R})$. Set

(5.34)
$$V_{\delta}(x) = V(x) - \int_0^x u^{\delta}(y) dy, x \in \mathbb{R}$$

Let $X^{\varepsilon,\delta}(\cdot)$ and $X^{\delta}(\cdot)$ denote respectively the solution to (5.3) and (5.1) corresponding to $u^{\delta}(\cdot)$. Let $\hat{\eta}^{\varepsilon,\delta}(dx)$ dnote the unique invariant probability measure of $X^{\varepsilon,\delta}(\cdot)$. Set

$$\hat{p}_{ii+1}^{\delta} = \frac{\sqrt{|V_{\delta}''(y_{m_{i-1}})|}}{\sqrt{|V_{\delta}''(y_{m_{i-1}})|} + \sqrt{|V_{\delta}''(y_{m_{i}})|}},$$
(5.35)
$$\hat{p}_{ii-1}^{\delta} = \frac{\sqrt{|V_{\delta}''(y_{m_{i-1}})|} + \sqrt{|V_{\delta}''(y_{m_{i}})|}}{\sqrt{|V_{\delta}''(y_{m_{i-1}})|} + \sqrt{|V_{\delta}''(y_{m_{i}})|}},$$

$$\hat{C}_{\delta} = \sum_{j=1}^{\kappa} \frac{1}{\sqrt{|V_{\delta}''(x_{m_{j}})|}},$$

$$\hat{\mu}^{\delta}(x_{m_{i}}) = \frac{1}{\hat{C}_{\delta}\hat{\mu}^{\delta}(x_{m_{1}})\sqrt{|V_{\delta}''(y_{m_{1}})|}},$$

$$\hat{\lambda}(i) = \frac{1}{\hat{C}_{\delta}\hat{\mu}^{\delta}(x_{m_{i}})} \left(\frac{1}{\sqrt{|V_{\delta}''(y_{m_{i-1}})|}} + \frac{1}{\sqrt{|V_{\delta}''(y_{m_{i}})|}}\right), i \ge 2,$$

$$(5.36)\hat{Q}^{\delta}(x_{m_{i}}, x_{m_{i+1}}) = \frac{1}{\hat{C}_{\delta}\hat{\mu}^{\delta}(x_{m_{i}})\sqrt{|V_{\delta}''(y_{m_{i}})|}}, i = 1, 2, \cdots, \kappa - 1,$$

$$\hat{Q}^{\delta}(x_{m_{i}}, x_{m_{i-1}}) = \frac{1}{\hat{C}_{\delta}\hat{\mu}^{\delta}(x_{m_{i}})\sqrt{|V_{\delta}''(y_{m_{i-1}})|}}, i = 2, \cdots, \kappa.$$

Let $\hat{Z}_{\delta}(\cdot)$ denote the continuous time Markov chain with state space S with rate matrix \hat{Q}^{δ} . Then the generator is given by for $i = 1, 2, \cdots, \kappa$,

$$(5.37) \ \hat{L}^{\delta}f(x_{m_i}) = \hat{\lambda}(i)\hat{p}_{ii-1}^{\delta}\left(f(x_{m_i}) - f(x_{m_{i-1}})\right) + \hat{\lambda}(i)\hat{p}_{ii+1}^{\delta}\left(f(x_{m_i}) - f(x_{m_{i+1}})\right).$$

Now by mimicking the analysis used to prove Theorem 5.7, it follows that $\hat{\eta}^{\varepsilon,\delta}(dx)$ converges to the unique invariant probability distribution $\hat{\mu}^{\delta}$ of $\hat{Z}_{\delta}(\cdot)$. Clearly $\hat{\mu}^{\delta}$

is an invariant probability distribution of $\hat{Z}_{\delta}(\cdot)$. Now

$$\int \bar{r}(x, u^{\delta}(x))\hat{\mu}^{\delta}(dx) \leq \rho^* + \delta.$$

Hence (H2) holds for u^0 .

Theorem 5.10. Assume (T). Then

$$\lim_{\delta \to 0} \lim_{\varepsilon \to 0} \rho_{\varepsilon}(x, u_{\delta}^{\varepsilon}(\cdot)) = \rho^*.$$

More over ρ^* is given by

$$\rho^* = \lim_{t \to \infty} \frac{1}{t} E \Big[\int_0^t r(Z(s), u^0(Z(s)) ds \Big].$$

Proof. Consider

$$\begin{split} \rho_{\varepsilon}(x, u_{\delta}^{\varepsilon}(\cdot) &= \liminf_{t \to \infty} \frac{1}{t} E \Big[\int_{0}^{t} r(X_{\delta}^{\varepsilon}(s), u_{\delta}^{\varepsilon}(X_{\delta}^{\varepsilon}(s)) ds \\ &= \int r(x, u_{\delta}^{\varepsilon}(x)) \eta^{\varepsilon, \delta}(dx) \\ &= \int (r(x, u_{\delta}^{\varepsilon}(x) - r(x, u_{\delta}^{0}(x)) \eta^{\varepsilon, \delta}(dx) + \int \bar{r}(x, u_{\delta}^{0}(x)) \eta^{\varepsilon, \delta}(dx) \end{split}$$

Since $u^\varepsilon_\delta \to u^0_\delta$ uniformly on compact sets, it follows from Lemma 5.8

$$\lim_{\varepsilon \to 0} \rho_{\varepsilon}(x, u_{\delta}^{\varepsilon}(\cdot)) = \int r(x, u_{\delta}^{0}(x)) \mu^{\delta}(dx).$$

Hence using (5.8), we get

$$\lim_{\varepsilon \to 0} \rho_{\varepsilon}(x, u^{\varepsilon}(\cdot)) = \lim_{\delta \to 0} \int r(x, u^{0}_{\delta}(x)) \mu^{\delta}(dx)$$
$$= \int r(x, u^{0}(x)) \mu(dx),$$

where $\mu(dx)$ is the unique invariant probability measure of $Z(\cdot)$ given in (5.32). The last equality follows since μ^{δ}, μ are supported on S. From Theorem 2.1 and Lemma 5.9, we have

$$\lim_{\varepsilon \to 0} \rho_{\varepsilon}(x, u^{\varepsilon}(\cdot)) = \rho^*.$$

Hence we get

(5.38)
$$\rho^* = \int r(x, u^0(x)) \mu(dx)$$

This completes the proof.

Lemma .11. Assume (A1). For any prescribed control $U(\cdot)$, let $X(\cdot)$ denote a unique solution to the sde (1.1). The semigroup $\{T_t : t \ge 0\}$ of $X(\cdot)$ satisfies the following. For each $f \in C_b^2(\mathbb{R}^d)$, $T_t f$ is Lipschitz continuous for each $t \ge 0$.

33

Proof. For $x_1, x_2 \in \mathbb{R}^d$, let $X(x_1; \cdot), X(x_2; \cdot)$ denote unique solutions to (1.1) corresponding to $U(\cdot)$ and initial conditions x_1, x_2 respectively. Now using Ito's formula we get for $f \in C_b^2(\mathbb{R}^d)$,

(.39) $df(X(x_i;t)) = \mathcal{L}^{U(t)}f(X(x_i;t))dt + \nabla f(X(x_i;t))\sigma(X(x_i;t))dW(t), i = 1, 2.$ Using (A1) and (.39), we have

$$\begin{aligned} |T_t f(x_1) - T_t f(x_2)| &= |Ef(X(x_1; t)) - Ef(X(x_2; t))| \\ &\leq |f(x_1) - f(x_2) + K_1 \int_0^t E ||X(x_1; s) - X(x_2; s)|| ds \\ &\leq K_2 ||x_1 - x_2||, \end{aligned}$$

where the last inequality follows from Remark 2.2.6, p.39, [1] and K_1, K_2 are constants which may depend on T, f but not on x_1, x_2 .

Lemma .12. Assume (A1). Consider the process $Z^{\varepsilon}(\cdot)$ given in Lemma 4.2. If $\mu^{\varepsilon} \in \mathcal{P}(\mathbb{R}^{3d})$ satisfies

$$\iiint \mathcal{L}_Z^{\varepsilon} f(z) \mu^{\varepsilon}(dz) = 0 \text{ for all } f \in C_c^{\infty}(\mathbb{R}^{3d}),$$

then μ^{ε} is an invariant probability measure of the process $Z^{\varepsilon}(\cdot)$.

Proof. For $f \in C_c^{\infty}(\mathbb{R}^{3d})$, using Itô's formula), we have

$$E_z f(Z_t^{\varepsilon}) = f(z) + \int_0^t E_z [\mathcal{L}_Z^{\varepsilon} f(Z_s^{\varepsilon})] ds$$

Define

$$T_t f(z) = E_z f(Z_t^{\varepsilon}), z \in \mathbb{R}^{3d}, t > 0, T_0 f = f.$$

Then $\{T_t : t \ge 0\}$ is a strongly continuous semigroup with generator $\mathcal{L}_Z^{\varepsilon}$. Then for $f \in \mathcal{D}(\mathcal{L}_Z^{\varepsilon})$, from Propostion 1.3.1, p.10, [1], we have

$$T_t f \in \mathcal{D}(\mathcal{L}_Z^{\varepsilon}), \ \mathcal{L}_Z^{\varepsilon}(T_t f) = T_t(\mathcal{L}_Z^{\varepsilon})$$

and

$$E_z f(X_t) = f(z) + \int_0^t \mathcal{L}_Z^{\varepsilon}(T_s f)(z) ds$$

Integrate the above with respect to μ^{ε} , we get

$$\iiint E_z f(Z_t^{\varepsilon}) \mu^{\varepsilon}(dz) = \iiint f(z) \mu^{\varepsilon}(dz) + \int_0^t \iiint \mathcal{L}_Z^{\varepsilon}(T_s f)(z) \mu^{\varepsilon}(dz) ds$$
$$= \iiint f(z) \mu^{\varepsilon}(dz).$$

The last equality holds, since $T_s f \in \mathcal{D}(\mathcal{L}_Z^{\varepsilon})$. In particular, since $C_c^{\infty}(\mathbb{R}^{3d}) \subseteq \mathcal{D}(\mathcal{L}_Z^{\varepsilon})$, we have

$$\iiint E_z f(Z_t^{\varepsilon}) \mu^{\varepsilon}(dz) = \iiint f(z) \mu^{\varepsilon}(dz) \text{ for all } f \in C_c^{\infty}(\mathbb{R}^{3d}), t > 0.$$

Hence μ^{ε} is an invariant probability measure for $Z^{\varepsilon}(\cdot)$.

Remark .13. The above result doesn't assume that process $Z^{\varepsilon}(\cdot)$ is Feller instead we assume $C_c^{\infty}(\mathbb{R}^{3d}) \subseteq \mathcal{D}(\mathcal{L}_Z^{\varepsilon})$ but the proof is standard. We give it for the sake completeness.
