Backward Map for Filter Stability Analysis

Jin Won Kim, Anant A. Joshi and Prashant G. Mehta

Abstract—In this paper, a backward map is introduced for the purposes of analysis of the nonlinear (stochastic) filter stability. The backward map is important because the filter-stability in the sense of χ^2 -divergence follows from showing a certain variance decay property for the backward map. To show this property requires additional assumptions on the model properties of the hidden Markov model (HMM). The analysis in this paper is based on introducing a Poincaré Inequality (PI) for HMMs with white noise observations. In finite state-space settings, PI is related to both the ergodicity of the Markov process as well as the observability of the HMM. It is shown that the Poincaré constant is positive if and only if the HMM is detectable.

I. Introduction

Dissipation is at the heart of any stability theory for dynamical systems. For Markov processes, dissipation is referred to as the *variance decay*. To illustrate the key ideas, consider a Markov process $X = \{X_t : t \ge 0\}$ taking values in a Polish state-space $\mathbb S$ and suppose $\bar{\mu}$ is a given invariant measure. The fundamental object of interest is the Markov semigroup defined by [1, Eq. (1.1.1)]

$$(P_t f)(x) := \mathsf{E}^{\bar{\mu}}(f(X_t)|[X_0 = x]), \quad x \in \mathbb{S}, \ t \ge 0$$

for $f: \mathbb{S} \to \mathbb{R}$ a suitable measurable function. The problem of stochastic stability is to show that $P_t f \to \bar{\mu}(f)$, in some suitable sense, as $t \to \infty$. As defined, $(P_t f)(x)$ has an interpretation as the expectation of the random variable $f(X_t)$ starting from initial condition $X_0 = x$. Therefore, $P_t f \to \bar{\mu}(f)$ means that this expectation asymptotically converges to its stationary value $\bar{\mu}(f)$ irrespective of the initial condition x.

In order to write a dissipation equation, the following definitions are introduced:

(variance):
$$\mathcal{V}^{\bar{\mu}}(f) \coloneqq \bar{\mu}(f^2) - \bar{\mu}(f)^2$$

(energy): $\mathcal{E}^{\bar{\mu}}(f) \coloneqq \bar{\mu}(\Gamma f)$

where Γ is the so called carré du champ operator. The operator is a positive-definite bilinear form (see Defn. 2). Using these definitions, the dissipation equation arises as

$$\frac{\mathrm{d}}{\mathrm{d}t}\mathcal{V}^{\bar{\mu}}(P_t f) = -\mathcal{E}^{\bar{\mu}}(P_t f), \quad t \ge 0$$

(The straightforward calculation for the same appears in Appendix A, see also [1, Thm. 4.2.5.)]). The equation

J. W. Kim is with the Institute of Mathematics at the University of Potsdam (e-mail: jin.won.kim@uni-potsdam.de).

A. A. Joshi and P. G. Mehta are with the Coordinated Science Laboratory and the Department of Mechanical Science and Engineering at the University of Illinois at Urbana-Champaign (e-mail: anantaj2; mehtapg@illinois.edu)

shows that $\{\mathcal{V}^{\bar{\mu}}(P_t f): t \geq 0\}$ is non-increasing. To show that the variance decays to zero requires a suitable relationship between energy and variance. The simplest such relationship is through the Poincaré Inequality (PI):

(PI)
$$\mathcal{E}^{\bar{\mu}}(f) \ge c \mathcal{V}^{\bar{\mu}}(f), \quad \forall f$$

where the sharpest such constant c is referred to as the Poincaré constant. PI is useful to conclude stochastic stability where c gives the exponential rate of convergence. For reversible Markov processes, c is referred to as the spectral gap constant.

A. Aims and contributions of this paper

This paper is concerned with extension of variance decay to the study of conditioned Markov processes (nonlinear filter). Specifically, the following questions are of interest:

- **Q1.** What is the appropriate notion of variance decay for a nonlinear filter? And how is it related to filter stability?
- **Q2.** What is the appropriate generalization of the dissipation equation for the nonlinear filter?
- **Q3.** What is the appropriate generalization of the Poincaré inequality for the filter? And how is it related to the hidden Markov model (HMM) properties such as observability and detectability?

In this paper, we provide an answer to each of these questions (see Prop. 1 for Q1, Prop. 2 for Q2, and Prop. 6-7 for Q3). An original contribution of this paper is the backward map that is introduced here for a general class of HMMs. The backward map is important because the filter stability – in the sense of χ^2 -divergence – follows from showing a certain variance decay property for the map. While the backward map and the variance decay is for a general class of HMMs, the answers to Q2 and Q3 are given for HMM with white noise observations. The overall approach may be regarded as an *optimal control approach* to filter stability based on our recent work on duality [2], [3], [4]. Our approach is contrasted with the intrinsic approach to filter stability based upon specification of a certain forward map [5].

B. Outline of the remainder of this paper

Sec. II contains math preliminaries for the HMM and the filter stability problem. The backward map is introduced in Sec. III and specialized to white noise observations in Sec. IV. For this HMM, the definition of the Poincaré Inequality (PI) is introduced in Sec. V. The PI is related to the HMM model properties in Sec. VI (for the finite state-space settings) and illustrated using numerics in Sec. VII. The proofs appear in the Appendix.

II. MATHEMATICAL PRELIMINARIES

A. Hidden Markov model (HMM)

For the definition and analysis of the nonlinear filter, a standard model for HMM is specified (see [6, Sec. 2]) through construction of a pair of stochastic processes (X,Z) on probability space $(\Omega, \mathcal{F}_T, \mathsf{P})$ as follows:

- The state-space S is a locally compact Polish space.
 The important examples are (i) S = {1,2,···,d} of finite or countable cardinality, and (ii) S ⊆ R^d.
- The observation-space $\mathbb{O} = \mathbb{R}^m$.
- The signal-observation process $(X,Z) := \{(X_t,Z_t) : 0 \le t \le T\}$ is a Feller-Markov process.
- The state process X is a Feller-Markov process. The prior is denoted by $\mu \in \mathcal{P}(\mathbb{S})$ such that $X_0 \sim \mu$. Here, $\mathcal{P}(\mathbb{S})$ is the space of probability measures defined on the Borel σ -algebra on \mathbb{S} .
- The observation process Z has $Z_0 = 0$ and conditionally independent increments given the state process X. That is, given X_t , an increment $Z_s Z_t$ is independent of $\mathcal{Z}_t := \sigma(\{Z_s : 0 \le s \le t\})$, for all s > t. The filtration generated by the observations is denoted $\mathcal{Z} := \{\mathcal{Z}_t : 0 \le t \le T\}$.

The objective of nonlinear (or stochastic) filtering is to compute the conditional expectation

$$\pi_T(f) := \mathsf{E}(f(X_T) \mid \mathcal{Z}_T), \quad f \in C_b(\mathbb{S})$$

where $C_b(\mathbb{S})$ is the space of continuous and bounded functions. The conditional expectation is referred to as the *nonlinear filter*.

B. Filter stability

Let $\rho \in \mathcal{P}(\mathbb{S})$. On the common measurable space (Ω, \mathcal{F}_T) , P^ρ is used to denote another probability measure such that the transition law of (X,Z) is identical but $X_0 \sim \rho$ (see [7, Sec. 2.2] for an explicit construction of P^ρ as a probability measure over paths on $\mathbb{S} \times \mathbb{O}$.). The associated expectation operator is denoted by $\mathsf{E}^\rho(\cdot)$ and the nonlinear filter by $\pi_t^\rho(f) = \mathsf{E}^\rho(f(X_t) \mid \mathcal{Z}_t)$. The two important choices for ρ are as follows:

- $\rho = \mu$. The measure μ has the meaning of the true prior.
- $\rho = v$. The measure v has the meaning of an incorrect prior that is used to compute the filter.

The relationship between P^{μ} and P^{ν} is as follows $(P^{\mu}|_{\mathcal{Z}_t})$ denotes the restriction of P^{μ} to the σ -algebra \mathcal{Z}_t):

Lemma 1 (Lemma 2.1 in [7]): Suppose $\mu \ll v$. Then

• $P^{\mu} \ll P^{\nu}$, and the change of measure is given by

$$\frac{dP^{\mu}}{dP^{\nu}}(\omega) = \frac{d\mu}{d\nu}(X_0(\omega)) \quad P^{\nu}\text{-a.s. } \omega$$

• For each t > 0, $\pi_t^{\mu} \ll \pi_t^{\nu}$, $\mathsf{P}^{\mu}|_{\mathcal{Z}_t}$ -a.s..

The following definition of filter stability is based on χ^2 -divergence¹ (Because μ has the meaning of the correct prior, the expectation is with respect to P^{μ}):

¹For any two probability measures $\mu, \nu \in \mathcal{P}(\mathbb{S})$ such that $\mu \ll \nu$, the χ^2 -divergence $\chi^2(\mu \mid \nu) := \int_{\mathbb{S}} (\frac{\mathrm{d}\mu}{\mathrm{d}\nu}(x) - 1)^2 \, \mathrm{d}\nu(x)$.

Definition 1: The nonlinear filter is stable in the sense of

$$(\chi^2 \text{ divergence}) \qquad \mathsf{E}^{\mu} \big(\chi^2 (\pi_T^{\mu} \mid \pi_T^{\nu}) \big) \longrightarrow 0$$

as $T \to \infty$ for every $\mu, \nu \in \mathcal{P}(\mathbb{S})$ such that $\mu \ll \nu$.

III. Backward map for the nonlinear filter Suppose $\mu \ll \nu$. Denote

$$\gamma_T(x) \coloneqq \frac{\mathrm{d}\pi_T^{\mu}}{\mathrm{d}\pi_T^{\nu}}(x), \quad x \in \mathbb{S}$$

It is well-defined because $\pi_T^{\mu} \ll \pi_T^{\nu}$ from Lem. 1 (we adopt here the convention that $\frac{0}{0} = 0$). It is noted that while $\gamma_0 = \frac{\mathrm{d}\mu}{\mathrm{d}\nu}$ is deterministic, γ_T is a \mathcal{Z}_T -measurable function on \mathbb{S} . Both of these are examples of likelihood ratio and referred to as such throughout the paper.

A key original concept introduced in this paper is the *backward map* $\gamma_T \mapsto y_0$ defined as follows:

$$y_0(x) := \mathsf{E}^{\nu}(\gamma_T(X_T)|[X_0 = x]), \quad x \in \mathbb{S}$$
 (1)

The function $y_0: \mathbb{S} \to \mathbb{R}$ is deterministic, non-negative, and $v(y_0) = \mathsf{E}^v(\gamma_T(X_T)) = 1$, and therefore is also a likelihood ratio.

Since $\mu \ll v$, it follows $\mu(y_0) = \mathsf{E}^{\mu}(\gamma_T(X_T))$. Using the tower property,

$$\mu(y_0) = \mathsf{E}^{\mu}(\gamma_T(X_T)) = \mathsf{E}^{\mu}(\pi_T^{\mu}(\gamma_T)) = \mathsf{E}^{\mu}(\pi_T^{\nu}(\gamma_T^2))$$

Noting that $\pi_T^{\nu}(\gamma_T^2) - 1 = \chi^2(\pi_T^{\mu} \mid \pi_T^{\nu})$ is the χ^2 -divergence,

$$\mathsf{E}^{\mu} (\chi^{2} (\pi_{T}^{\mu} \mid \pi_{T}^{\nu})) = \mu(y_{0}) - \nu(y_{0})$$

Therefore, filter stability in the sense of χ^2 -divergence is equivalent to showing that $\mu(y_0) \stackrel{(T \to \infty)}{\longrightarrow} 1$.

Because $\mu(y_0) - \nu(y_0) = \nu((\gamma_0 - 1)(y_0 - 1))$, upon using the Cauchy-Schwarz inequality,

$$|\mathsf{E}^{\mu}(\chi^{2}(\pi_{T}^{\mu} \mid \pi_{T}^{\nu}))|^{2} \le \mathrm{var}^{\nu}(y_{0}(X_{0})) \chi^{2}(\mu \mid \nu)$$
 (2)

where $\operatorname{var}^{\nu}(y_0(X_0)) = \mathsf{E}^{\nu}(|y_0(X_0) - 1|^2)$.

From (2), provided $\chi^2(\mu|\nu) < \infty$, a sufficient condition for filter stability is the following:

(variance decay prop.)
$$\operatorname{var}^{\nu}(y_0(X_0)) \stackrel{(T \to \infty)}{\longrightarrow} 0$$
 (3)

We have thus shown the following:

Proposition 1 (Answer to Q1 in Sec. 1): Consider the backward map $\gamma_T \mapsto y_0$ defined by (1). Suppose $\chi^2(\mu|\nu) < \infty$ and the variance decay property (3) holds. Then the filter is stable in the sense of χ^2 -divergence.

Next, from (1), $(y_0(X_0) - 1) = \mathsf{E}^{\nu}((\gamma_T(X_T) - 1)|X_0)$, and using Jensen's inequality,

$$\operatorname{var}^{\nu}(y_0(X_0)) \le \operatorname{var}^{\nu}(\gamma_T(X_T)) \tag{4}$$

where $\operatorname{var}^{V}(\gamma_{T}(X_{T})) := \mathsf{E}^{V}(|\gamma_{T}(X_{T}) - 1|^{2})$. Therefore, the backward map $\gamma_{T} \mapsto y_{0}$ is non-expansive – the variance of the random variable $y_{0}(X_{0})$ is smaller than the variance of the random variable $\gamma_{T}(X_{T})$.

Based on the backward map, the analysis of filter stability involves the following objectives:

- 1) To express a stronger form of (4) such that the variance decay property (3) is deduced under a suitable definition of the Poincaré inequality (PI).
- Relate PI to the model properties, namely, (i) ergodicity of the Markov process; and (ii) observability of the HMM.

While the general case remains open, these objectives are described for the special class of HMMs with white noise observations.

The following subsection is included to help relate the approach of this paper to the literature. The reader may choose to skip ahead to Sec. IV without any loss of continuity.

A. Comparison with the forward map

The backward map is contrasted with the *forward map* which is the starting point of the intrinsic approach to the problem of filter stability [5]. The *forward map* $\gamma_0 \mapsto \gamma_T$ is defined as follows:

$$\gamma_T(x) = \mathsf{E}^{\mathsf{V}}\Big(\frac{\gamma_0(X_0)}{\mathsf{E}^{\mathsf{V}}(\gamma_0(X_0) \mid \mathcal{Z}_T)}\bigg| \mathcal{Z}_T \vee [X_T = x]\Big), \quad x \in \mathbb{S}$$

Upon using the map to express the total variation, one obtains

$$\lim_{T\to\infty}\mathsf{E}^\mu\big(\|\pi_T^\mu-\pi_T^\nu\|_{\scriptscriptstyle \mathrm{TV}}\big)=$$

$$\mathsf{E}^{\mathsf{v}}\Big(\Big|\mathsf{E}^{\mathsf{v}}\big(\gamma_{\!0}(X_0)\,|\bigcap_{T\geq 0}\mathcal{Z}_{\infty}\vee\mathcal{F}^X_{[T,\infty)}\big)-\mathsf{E}^{\mathsf{v}}\big(\gamma_{\!0}(X_0)\,|\,\mathcal{Z}_{\infty}\big)\Big|\Big)$$

where $\mathcal{Z}_{\infty} = \bigcup_{T>0} \mathcal{Z}_T$, $\mathcal{F}^X_{[T,\infty)} = \sigma(\{X_t - X_T : t \ge T\})$ is the tail sigma-algebra of the state process X. As a function of T, $\mathcal{Z}_{\infty} \vee \mathcal{F}^X_{[T,\infty)}$ is a decreasing filtration and \mathcal{Z}_T is an increasing filtration, and this both terms on the right-hand side converge as $T \to \infty$, The right-hand side is zero if the following tail sigma field identity:

$$\bigcap_{T\geq 0}\mathcal{Z}_{\infty}\vee\mathcal{F}^{X}_{[T,\infty)}\stackrel{?}{=}\mathcal{Z}_{\infty}$$

This identity is referred to as the central problem in the stability analysis of the nonlinear filter [8]. The problem generated large consequent attention (see [9] and references therein).

IV. EMBEDDING THE BACKWARD MAP IN A BSDE

A. White noise observation model

In the remainder of this paper, the observation process *Z* is according to the stochastic differential equation (SDE):

$$Z_t = \int_0^t h(X_s) \, \mathrm{d}s + W_t, \quad t \ge 0 \tag{5}$$

where $h: \mathbb{S} \to \mathbb{R}^m$ is referred to as the observation function and $W = \{W_t : 0 \le t \le T\}$ is an *m*-dimensional Brownian motion (B.M.). We write W is P-B.M. It is assumed that W is independent of X.

For the ensuing analysis, we also need to specify additional notation for the Markov process X. Specifically, the infinitesimal generator of the Markov process X is denoted by A. In terms of A, an important definition is as follows:

Definition 2 (Defn. 1.4.1. in [1]): The bilinear operator

$$\Gamma(f,g)(x) := (\mathcal{A}fg)(x) - f(x)(\mathcal{A}g)(x) - g(x)(\mathcal{A}f)(x), x \in \mathbb{S}$$

defined for every $(f,g) \in \mathcal{D} \times \mathcal{D}$ is called the *carré du champ operator* of the Markov generator \mathcal{A} . Here, \mathcal{D} is a vector space of (test) functions that are dense in L^2 , stable under products (i.e., \mathcal{D} is an algebra), and $\Gamma: \mathcal{D} \times \mathcal{D} \to \mathcal{D}$ (i.e., Γ maps two functions in \mathcal{D} into a function in \mathcal{D}), such that $\Gamma(f,f) \geq 0$ for every $f \in \mathcal{D}$ [1, Defn. 3.1.1]. $(\Gamma f)(x) := \Gamma(f,f)(x)$.

The above is referred to as the *white noise observation model* of nonlinear filtering. The model is denoted by (A,h).

Because these were stated piecemeal, the main assumptions are stated as follows:

Assumption 1: Consider HMM (A, h).

- 1) X is a Feller-Markov process with generator A and carré du champ Γ .
- 2) Z is according to the SDE (5) such that the Novikov's condition holds:

$$\mathsf{E}\left(\exp\left(\frac{1}{2}\int_0^T |h(X_t)|^2 dt\right)\right) < \infty$$

The condition holds, e.g., if $h \in C_b(\mathbb{S})$.

3) $\mu, \nu \in \mathcal{P}(\mathbb{S})$ are two priors with $\mu \ll \nu$.

For the HMM (A,h), the nonlinear filter solves the celebrated *Kushner-Stratonovich equation*:

$$d\pi_t(f) = \pi_t(\mathcal{A}f)dt + (\pi_t(hf) - \pi_t(f)\pi_t(h))^{\mathrm{T}}dI_t$$
 (6)

where the innovation process is defined by

$$I_t := Z_t - \int_0^t \pi_s(h) \, \mathrm{d} s, \quad t \ge 0$$

With $\pi_0 = \rho \in \mathcal{P}(\mathbb{S})$, the filter $\{\pi_t^{\rho}(f) : 0 \le t \le T\}$ is the solution of (6). Therefore, for the HMM (\mathcal{A}, h) , the likelihood ratio γ_T is the ratio of the solution of (6), π_T^{μ} and π_T^{ν} , with the two choices of priors, $\pi_0 = \mu$ and $\pi_0 = \nu$, respectively.

B. Embedding the backward map in a BSDE

We continue the analysis of the backward map $\gamma_T \mapsto y_0$ introduced as (1) in Sec. III. For this purpose, consider the backward stochastic differential equation (BSDE):

$$-dY_t(x) = ((\mathcal{A}Y_t)(x) + h^{\mathsf{T}}(x)V_t(x))dt - V_t^{\mathsf{T}}(x)dZ_t,$$

$$Y_T(x) = \gamma_T(x), \ x \in \mathbb{S}, \ 0 \le t \le T$$
(7)

Here $(Y,V) = \{(Y_t(x),V_t(x)) : \Omega \to \mathbb{R} \times \mathbb{R}^m : x \in \mathbb{S}, 0 \le t \le T\}$ is a \mathbb{Z} -adapted solution of the BSDE for a prescribed \mathbb{Z}_T -measurable terminal condition $Y_T = \gamma_T = \frac{\mathrm{d} \pi_T^\mu}{\mathrm{d} \pi_T^\nu}$.

For the HMM (A,h), the relationship between the BSDE (7) and the backward map (1) is given of the following proposition:

Proposition 2 (Answer to Q2 in Sec. I): Consider (7). Then at time t = 0,

$$Y_0(x) = y_0(x), \quad x \in \mathbb{S}$$

where y_0 is according to the backward map (1). Also,

$$\frac{\mathrm{d}}{\mathrm{d}t} \mathrm{var}^{\nu} (Y_t(X_t)) = \mathsf{E}^{\nu} (\pi_t^{\nu} (\Gamma Y_t) + \pi_t^{\nu} (|V_t|^2)), \quad 0 \le t \le T \quad (8)$$

where $\operatorname{var}^{V}(Y_{t}(X_{t})) := \operatorname{E}^{V}(|Y_{t}(X_{t}) - 1|^{2})$ and $\pi_{t}^{V}(|V_{t}|^{2}) := \int_{\mathbb{S}} V_{t}^{\mathsf{T}}(x)V_{t}(x) \, \mathrm{d}\pi_{T}^{V}(x)$. (Eq. (8) is an example of a dissipation equation, and therefore an answer to question Q2 in Sec. I.)

Remark 1 (Relationship to (4)): Upon integrating (8),

$$\operatorname{var}^{v}(Y_{0}(X_{0})) + \operatorname{\mathsf{E}}^{v}\left(\int_{0}^{T} \pi_{t}^{v}(\Gamma Y_{t}) + \pi_{t}^{v}(|V_{t}|^{2}) \,\mathrm{d}t\right)$$
$$= \operatorname{var}^{v}(\gamma_{T}(X_{T})) \tag{9}$$

which is the stronger form of the inequality $\operatorname{var}^{\nu}(y_0(X_0)) \leq \operatorname{var}^{\nu}(\gamma_T(X_T))$ first obtained (see (4)) using the Jensen's inequality.

Either of the two equations, (8) or (9), is useful to show the variance decay property under suitable additional conditions on the model. The most straightforward of these conditions is the conditional Poincaré inequality (c-PI) introduced in an early paper [10] on this topic:

(c-PI)
$$\pi_t^{\bar{\mu}}(\Gamma f) \ge c \, \pi_t^{\bar{\mu}}(|f - \pi_t^{\bar{\mu}}(f)|^2) \quad \forall \, f \in \mathcal{D}, \, t \ge 0$$

Based upon c-PI, the following result is shown:

Proposition 3 (Thm. 1 in [10]): Suppose c-PI holds with constant c. Let $\underline{a} := \operatorname{essinf}_{x \in \mathbb{S}} \frac{\mathrm{d}\mu}{\mathrm{d}\bar{u}}(x)$. Then

$$\mathsf{E}^{\mu} \Big(\chi^2 \big(\pi_T^{\mu} \mid \pi_T^{\bar{\mu}} \big) \Big) \leq \frac{1}{a} e^{-cT} \chi^2 \big(\mu \mid \bar{\mu} \big)$$

Remark 2: In the conference paper [10], a few cases of HMM are described where the c-PI can be verified. This includes the case where the Markov process is Doeblin.

Our aim in the remainder of this paper is to define appropriate notions of energy, variance, and Poincaré Inequality (PI) for HMM (Defn. 3) and relate the PI to the model properties (Sec. VI).

V. POINCARÉ INEQUALITY (PI) FOR HMM

A. Function spaces and notation

Let $\rho \in \mathcal{P}(\mathbb{S})$ and $\tau > 0$. These are used to denote a generic prior and a generic time-horizon $[0, \tau]$. (In the analysis of filter stability, these are fixed to $\rho = \nu$ and $\tau = T$). The space of Borel-measurable deterministic functions is denoted

$$L^{2}(\rho) = \{ f : \mathbb{S} \to \mathbb{R} : \rho(f^{2}) = \int_{\mathbb{S}} |f(x)|^{2} d\rho(x) < \infty \}$$

Background from nonlinear filtering: A standard approach is based upon the Girsanov change of measure. Because the Novikov's condition holds, define a new measure \tilde{P}^{ρ} on $(\Omega, \mathcal{F}_{\tau})$ as follows:

$$\frac{\mathrm{d}\tilde{\mathsf{P}}^{\rho}}{\mathrm{d}\mathsf{P}^{\rho}} = \exp\left(-\int_{0}^{\tau} h^{\mathsf{T}}(X_{t}) \,\mathrm{d}W_{t} - \frac{1}{2} \int_{0}^{\tau} |h(X_{t})|^{2} \,\mathrm{d}t\right) =: D_{\tau}^{-1}$$

Then the probability law for X is unchanged but Z is a $\tilde{\mathsf{P}}^{\rho}$ -B.M. that is independent of X [11, Lem. 1.1.5]. The expectation with respect to $\tilde{\mathsf{P}}^{\rho}$ is denoted by $\tilde{\mathsf{E}}^{\rho}(\cdot)$. The

unnormalized filter $\sigma_{\tau}^{\rho}(f) \coloneqq \tilde{\mathsf{E}}^{\rho}(D_{\tau}f(X_{\tau})|\mathcal{Z}_{\tau})$ for $f \in C_b(\mathbb{S})$. It is called as such because $\pi_{\tau}^{\rho}(f) = \frac{\sigma_{\tau}^{\rho}(f)}{\sigma_{\tau}^{\rho}(1)}$. The measure-valued process $\{\sigma_t^{\rho}: 0 \le t \le \tau\}$ is the solution of the DMZ equation.

- Hilbert space for the dual: Formally, the "dual" is a function on the state-space. The space of such functions is denoted as \mathcal{Y} . For the case when $\mathbb{S} = \{1, 2, \dots, d\}$, $\mathcal{Y} = \mathbb{R}^d$. Related to the dual, two types of Hilbert spaces are of interest. These are defined as follows:
 - Hilbert space of \mathcal{Z}_{τ} -measurable random functions:

$$\mathbb{H}^{\rho}_{\tau} \coloneqq \{ F : \Omega \to \mathcal{Y} \, : \, F \in \mathcal{Z}_{\tau} \, \& \, \tilde{\mathsf{E}}^{\rho}(\sigma^{\rho}_{\tau}(F^2)) < \infty \}$$

(This function space is important because the backward map (1) is a map from $\gamma_T \in \mathbb{H}^{\nu}_T$ to $y_0 \in L^2(\nu)$).

Hilbert space of Y-valued Z-adapted stochastic processes:

$$\mathbb{H}^{\rho}([0,\tau]) := \{ Y : \Omega \times [0,\tau] \to \mathcal{Y} : Y_t \in \mathcal{Z}_t, \ 0 \le t \le \tau, \\ & \& \ \tilde{\mathsf{E}}^{\rho}\left(\int_0^{\tau} \sigma_t^{\rho}(Y_t^2) \, \mathrm{d}t\right) < \infty \}$$

(This function space is important because we will embed the backward map (1) $\gamma_T \mapsto y_0$ into a \mathcal{Y} -valued \mathcal{Z} -adapted stochastic process $Y = \{Y_t : \Omega \to \mathcal{Y} : 0 \le t \le T\}$ such that $Y_T = \gamma_T$ and $Y_0 = y_0$).

Notation: Let $\rho \in \mathcal{P}(\mathbb{S})$. For real-valued functions $f, g \in \mathcal{Y}$, $\mathcal{V}_t^{\rho}(f,g) \coloneqq \pi_t^{\rho}((f - \pi_t^{\rho}(f))(g - \pi_t^{\rho}(g)))$. With f = g, $\mathcal{V}_t^{\rho}(f) \coloneqq \mathcal{V}_t^{\rho}(f,f)$.

B. BSDE formulation for nonlinear filtering

In a prior work, we introduced a dual optimal control formulation of the nonlinear filter for the HMM (A,h) [3]. The formulation is used to introduce the following dual optimal control system:

Dual optimal control system:

$$-dY_{t}(x) = ((AY_{t})(x) - h^{\mathsf{T}}(x)\mathcal{V}_{t}^{\rho}(h, Y_{t}) + h^{\mathsf{T}}(x)(V_{t}(x) - \pi_{t}^{\rho}(V_{t})))dt - V_{t}^{\mathsf{T}}(x)dZ_{t} Y_{\tau}(x) = F(x), \ x \in \mathbb{S}, \ 0 \le t \le \tau$$

$$(10)$$

 $(Y,V) \in \mathbb{H}^{\rho}([0,\tau]) \times \mathbb{H}^{\rho}([0,\tau])^m$ is the solution of (10) for a given $F \in \mathbb{H}^{\rho}_{\tau}$. The dual optimal control system is important because of the following relationship to the nonlinear filter:

Proposition 4 (Prop. 1 in [3]): Consider (10). Then for each $t \in [0, \tau]$,

$$\pi_t^{\rho}(Y_t) = \rho(Y_0) + \int_0^t \left(\mathcal{V}_s^{\rho}(h, Y_s) + \pi_s^{\rho}(V_s) \right)^{\mathsf{T}} dZ_s \tag{11a}$$

$$\mathsf{E}^{\rho}\big(\mathcal{V}_{t}^{\rho}(Y_{t})\big) = \tag{11b}$$

$$\operatorname{var}^{\rho}(Y_{0}(X_{0})) + \mathsf{E}^{\rho}\left(\int_{0}^{t} \pi_{s}^{\rho}(\Gamma Y_{s}) + |\mathcal{V}_{s}^{\rho}(h, Y_{s})|^{2} + \mathcal{V}_{s}^{\rho}(V_{s}) \,\mathrm{d}s\right)$$

Remark 3: The BSDE embedding (7) of the backward map (1) is a special case of (10). In particular, with $F = \gamma_T$, using (11a) with $\tau = T$ and $\rho = v$,

$$V_t^{\nu}(h, Y_t) + \pi_t^{\nu}(V_t) = 0$$
, P^{ν} -a.s., $0 \le t \le T$

Therefore, (10) reduces to (7).

C. Definitions of energy, variance, and PI

Let $\mathcal{N} := \{ \rho \in \mathcal{P}(\mathbb{S}) : \text{var}^{\rho}(Y_0(X_0)) = 0 \ \forall F \in \mathbb{H}_{\tau}^{\rho} \}.$ *Definition 3:* Consider (10). *Energy* is defined as follows:

$$\mathcal{E}^{\rho}(F) \coloneqq \frac{1}{\tau} \mathsf{E}^{\rho} \left(\int_{0}^{\tau} \pi_{t}^{\rho}(\Gamma Y_{t}) + |\mathcal{V}_{t}^{\rho}(h, Y_{t})|^{2} + \mathcal{V}_{t}^{\rho}(V_{t}) \, \mathrm{d}t \right)$$

and the Poincaré constant is defined as follows:

$$c^{\rho} := \begin{cases} \inf \{ \mathcal{E}^{\rho}(F) : F \in \mathbb{H}^{\rho}_{\tau} \& \operatorname{var}^{\rho}(Y_{0}(X_{0})) = 1 \}, \\ \rho \in \mathcal{P}(\mathbb{S}) \setminus \mathcal{N} \\ +\infty, & \rho \in \mathcal{N} \end{cases}$$

When the Poincaré constant c^{ρ} is strictly positive the resulting inequality is the Poincaré inequality (PI) for the filter:

(PI)
$$\mathcal{E}^{\rho}(F) \geq c^{\rho} \operatorname{var}^{\rho}(Y_0(X_0)) \quad \forall F \in \mathbb{H}^{\rho}_{\tau}$$

D. Existence and regularity theory for c^{ρ}

We are interested in existence of the minimizers of the energy functional $\mathcal{E}^{\rho}(F)$ for $F \in \mathbb{H}^{\rho}_{\tau}$. If it exists, a minimizer is not unique because of the following translation symmetry:

$$\mathcal{E}^{\rho}(F+\alpha 1)=\mathcal{E}^{\rho}(F)$$

for any \mathcal{Z}_{τ} -measurable random variable α such that $\tilde{\mathsf{E}}^{\rho}(\alpha^2) < \infty$. For this reason, consider the subspace

$$S^{\rho} := \{ F \in \mathbb{H}^{\rho}_{\tau} : \pi^{\rho}_{\tau}(F) = 0, \ \mathsf{P}^{\rho} - a.s. \}$$

Then S^{ρ} is closed subspace. (Suppose $F^{(n)} \to F$ in \mathbb{H}^{ρ}_{τ} with $\pi^{\rho}_{\tau}(F^{(n)}) = 0$. Then $\mathsf{E}^{\rho}(|\pi^{\rho}_{\tau}(F)|) = \mathsf{E}^{\rho}(|\pi^{\rho}_{\tau}(F - F^{(n)})|) \le \mathsf{E}^{\rho}(\pi^{\rho}_{\tau}(|F - F^{(n)}|^2)) = ||F - F^{(n)}||_{\mathbb{H}^{\rho}_{\tau}} \to 0$.)

Proposition 5: Consider the optimal control system (10) with $Y_T = F \in S^p$. Then $\rho(Y_0) = 0$ and

$$V_t^{\rho}(h, Y_t) + \pi_t^{\rho}(V_t) = 0$$
, P^{ρ} -a.s., $0 \le t \le \tau$

Proof: The result follows from using (11a) in Prop. 4 (similar to Rem. 3).

Because of Prop. 5, for $Y_T = F \in \mathcal{S}^{\rho}$, (10) simplifies to

$$-dY_t(x) = ((\mathcal{A}Y_t)(x) + h^{\mathsf{T}}(x)V_t(x))dt - V_t^{\mathsf{T}}(x)dZ_t,$$

$$Y_{\tau} = F \in \mathcal{S}^{\rho}, \ x \in \mathbb{S}, \ 0 \le t \le \tau$$
(12)

Note that this is identical to the BSDE embedding (7) of the backward map. Its solution is used to define a linear operator as follows:

$$L_0: \mathcal{S}^{\rho} \subset \mathbb{H}^{\rho}_{\tau} \to L^2(\rho)$$
 by $L_0(F) := Y_0$

(It is noted that (12) and therefore L_0 do not depend upon ρ even though the optimal control system (10) does). Additional details concerning this operator appear in Appendix C where it is shown that L_0 is bounded with $||L_0|| \le 1$.

The following Lemma shows when a minimizer exists: Lemma 2: Let $\rho \in \mathcal{P}(\mathbb{S}) \setminus \mathcal{N}$. Suppose that L_0 is compact. Then there exists an $F \in \mathcal{S}^{\rho}$ such that

$$c^{\rho} = \mathcal{E}^{\rho}(F)$$
 and $\operatorname{var}^{\rho}(Y_0(X_0)) = 1$

Proof: See Appendix C.

VI. PI AND HMM MODEL PROPERTIES

In this section, we make the following assumption:

Assumption 2: The state-space is finite:

(A2)
$$S = \{1, 2, \dots, d\}$$

Definition 4: The space of observable functions is the smallest subspace $\mathcal{O} \subset \mathbb{R}^d$ that satisfies the following two properties:

- 1) The constant function $1 \in \mathcal{O}$; and
- 2) If $g \in \mathcal{O}$ then $Ag \in \mathcal{O}$ and $gh \in \mathcal{O}$.

The space of null eigenfunctions is defined as

$$S_0 := \{ f \in \mathbb{R}^d \mid \Gamma f(x) = 0 \ \forall \ x \in \mathbb{S} \}$$

Definition 5: Consider the HMM (A,h) on finite statespace.

- 1) The HMM (A,h) is observable if $\mathcal{O} = \mathbb{R}^d$.
- 2) A is ergodic if

$$\Gamma f(x) = 0, \ \forall \ x \in \mathbb{S} \implies f(x) = c, \ \forall \ x \in \mathbb{S}$$

3) The HMM (A, h) is detectable if $S_0 \subset \mathcal{O}$.

A. Main result

Proposition 6 (Answer to Q3 in Sec. I): Consider the HMM (A,h) on finite state-space and $\rho \in \mathcal{P}(\mathbb{S}) \setminus \mathcal{N}$. Suppose any one of the following conditions holds:

- 1) A is ergodic; or
- 2) (A,h) is observable; or
- 3) (A,h) is detectable.

Then $c^{\rho} > 0$.

The converse of this result which also gives the tightest condition for c^{ρ} to be positive is given in the following:

Proposition 7 (Answer to Q3 in Sec. I): Consider the HMM (A,h) on finite state-space. If $c^{\rho} > 0$ for all $\rho \in \mathcal{P}(\mathbb{S}) \setminus \mathcal{N}$, then (A,h) is detectable.

VII. NUMERICAL EXAMPLE

Consider an HMM on $\mathbb{S} = \{1, 2, 3, 4\}$ with the transition rate matrix is given by

$$A(\varepsilon) = \begin{pmatrix} -1 & 1 & 0 & 0 \\ 2 & -2 & 0 & 0 \\ 0 & 0 & -1 & 1 \\ 0 & 0 & 2 & -2 \end{pmatrix} + \varepsilon \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & -1 & 1 & 0 \\ 0 & 1 & -1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

With ε = 0, The state space has two separated communicating classes: $\{1,2\}$ and $\{3,4\}$. Therefore the state process is not ergodic. Choosing $\varepsilon > 0$ makes the bridge between the two and therefore the state process becomes ergodic.

Consider three options for the observation function:

$$h_1 = \begin{pmatrix} 2 \\ 0 \\ 2 \\ 0 \end{pmatrix}, \quad h_2 = \begin{pmatrix} 2 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \quad h_3 = \begin{pmatrix} 2 \\ 0 \\ -2 \\ 0 \end{pmatrix}$$

TABLE I COMBINATIONS OF SIMULATION PARAMETERS

ε	h	Model property	Rate of conv.
0	h_1	Not detectable	0
0	h_2	Non-ergodic but detectable	0.075
0	h_3	Observable	0.155
0.1	h_1	Ergodic with $h(1) = h(3)$	0.196
0.1	h_3	Ergodic with $h(1) \neq h(3)$	0.412

 χ^2 divergence between π_t^μ and π_t^ν

Fig. 1. $\chi^2(\pi_t^\mu \mid \pi_t^\nu)$ for the model with different values of ε and observation function. The number on each line shows the exponential rate obtained from linear fitting.

If $\varepsilon = 0$ and $h(1) = h(3) \neq 0$ (case h_1), then the system becomes not observable, as those two communicating classes are indistinguishable. If $h(1) \neq h(3)$ and both values are non-zero (case h_3), then the system becomes observable. Meanwhile, if one of the value is zero, the system becomes not observable, but still detectable as far as $h(1) \neq h(3)$ (case h_2).

Fig. 1 depicts the χ^2 -divergence between π_t^{μ} and π_t^{ν} from $\mu = [0.25, 0.40, 0.30, 0.05]$ and $\nu = [0.1, 0.2, 0.3, 0.4]$. The choice of parameters and the estimated rate of convergence are summarized in table VII. Simple Euler discretization with step size 0.005 is used, and the expectation is obtained by averaging over 500 Monte-Carlo simulations.

APPENDIX

A. Dissipation equation for a Markov process

The semigroup $\{P_t: t \ge 0\}$ is a solution of the Kolmogorov equation:

$$\frac{\partial}{\partial t}(P_t f)(x) = \mathcal{A}(P_t f)(x)$$

Therefore.

$$\frac{\mathrm{d}}{\mathrm{d}t} \mathcal{V}^{\bar{\mu}}(P_t f) = \bar{\mu} \Big(2(P_t f)(\partial_t P_t f) \Big) - 2\bar{\mu}(P_t f) \bar{\mu} \Big(\partial_t P_t f \Big) \\
= 2\bar{\mu} \Big((P_t f)(\mathcal{A}(P_t f)) \Big) - 2\bar{\mu}(P_t f) \bar{\mu} \Big(\mathcal{A}(P_t f) \Big) \\
= -\bar{\mu} (\Gamma(P_t f))$$

The last equation is because $\bar{\mu}(Ag) = 0$ for any g in the domain of the generator.

B. Proof of Proposition 2

Apply Itô formula on $Y_t(X_t)$ to obtain

$$dY_t(X_t) = V_t^{\mathsf{T}}(X_t) \left(dZ_t - h(X_t) dt \right) + (\text{m.g. associated with } \mathcal{A})$$

=: $V_t^{\mathsf{T}}(X_t) dW_t + dN_t$

where $\{N_t: t \ge 0\}$ is a martingale associated with A. Integrating this from some t to T yields

$$\gamma_T(X_T) = Y_t(X_t) + \int_t^T V_s^{\mathsf{T}}(X_s) \, \mathrm{d}W_s + \mathrm{d}N_t \tag{13}$$

and therefore

$$Y_t(x) = \mathsf{E}^{\mathsf{v}}(\gamma_T(X_T) \mid \mathcal{Z}_t \vee [X_t = x]), \quad x \in \mathbb{S}$$

In particular at time t = 0, we have $Y_0(x) = y_0(x)$ by definition. The variance of $Y_t(X_t)$ is also obtained from (13):

$$E^{V}(|\gamma_{T}(X_{T}) - 1|^{2})$$

$$= E^{V}(|Y_{t}(X_{t}) - 1|^{2} + \int_{t}^{T} |V_{s}(X_{s})|^{2} + (\Gamma Y_{s})(X_{s}) ds)$$

$$= \operatorname{var}^{V}(Y_{t}(X_{t})) + E^{V}(\int_{t}^{T} \pi_{s}^{V}(\Gamma Y_{s}) + \pi_{s}^{V}(|V_{s}|^{2}) ds)$$

Hence we obtain (8) by differentiation.

C. Proof of Lemma 2

Discussions on the map L_0 and \mathcal{E}^{ρ} : For $F \in \mathbb{H}^{\rho}_{\tau}$, note that

$$\|F\|_{\mathbb{H}^{\rho}}^{2} = \tilde{\mathsf{E}}^{\rho} \left(\sigma_{\tau}^{\rho}(F^{2})\right) = \mathsf{E}^{\rho} \left(\pi_{\tau}^{\rho}(F^{2})\right) = \mathsf{E}^{\rho} \left(F(X_{\tau})^{2}\right)$$

For $F \in \mathcal{S}^{\rho}$, $\pi_{\tau}(F) = 0$ and therefore

$$\mathsf{E}^{\rho}(F(X_{\tau})^2) = \mathsf{E}^{\rho}(\mathcal{V}^{\rho}_{\tau}(F))$$

From Prop. 4, we obtain

$$||F||_{\mathbb{H}^{\rho}}^{2} = \operatorname{var}^{\rho}(Y_{0}(X_{0})) + \tau \mathcal{E}^{\rho}(F), \quad F \in \mathcal{S}^{\rho}$$
 (14)

Since $\rho(Y_0) = 0$, $||Y_0||_{\mathbb{H}^{\rho}_{\tau}}^2 = \text{var}^{\rho}(Y_0(X_0))$ and this proves L is bounded with $||L_0|| \le 1$.

To obtain the minimizer, setting (\tilde{Y}, \tilde{V}) be the solution to (12) with $Y_{\tau} = \tilde{F} \in \mathcal{S}^{\rho}$, the functional derivative is evaluated as follows:

$$\langle \nabla \mathcal{E}^{\rho}(F), \tilde{F} \rangle \coloneqq \frac{2}{\tau} \mathsf{E}^{\rho} \left(\int_{0}^{\tau} \pi_{t}^{\rho} (\Gamma(Y_{t}, \tilde{Y}_{t}) + \pi_{t}^{\rho}(V_{t}^{\mathsf{T}} \tilde{V}_{t}) \, \mathrm{d}t \right)$$

where note $\pi_t^{\rho}(V_t^{\mathsf{T}}\tilde{V}_t) \coloneqq \int_{\mathbb{S}} V_t^{\mathsf{T}}(x) \tilde{V}_t(x) \, \mathrm{d}\pi_t^{\rho}(x)$. From the Cauchy-Schwarz formula and (14),

$$|\langle \nabla \mathcal{E}^{\rho}(F), \tilde{F} \rangle|^{2} \leq \frac{4}{\tau} \mathcal{E}^{\rho}(F) \|\tilde{F}\|_{\mathbb{H}^{\rho}_{\tau}}^{2} \tag{15}$$

This shows that $\tilde{F} \mapsto \langle \nabla \mathcal{E}^{\rho}(F), \tilde{F} \rangle$ is a bounded linear functional as a map from $\mathcal{S}^{\rho} \subset \mathbb{H}^{\rho}_{\tau}$ into \mathbb{R} . With these formalities completed, we show a minimizer exists.

Proof of Lemma 2: By definition of c^{ρ} , we consider a sequence of functions $\{F^{(n)} \in \mathcal{S}^{\rho} : n = 1, 2, ...\}$ such that $\mathcal{E}^{\rho}(F^{(n)}) \downarrow c^{\rho}$ and $\rho((Y_0^{(n)})^2) = 1$ for each n, with $Y_0^{(n)} := \mathsf{L}_0(F^{(n)})$. Assume $\mathcal{E}^{\rho}(F_1) < c^{\rho} + 1$, and then apply (14) to obtain

$$||F^{(n)}||_{\mathbb{H}^{\rho}_{\tau}}^{2} = 1 + \tau \mathcal{E}^{\rho}(F^{(n)}) < 1 + \tau(c^{\rho} + 1), \quad n = 1, 2, \dots$$

Therefore $F^{(n)}$ is a bounded sequence in the Hilbert space \mathbb{H}^{ρ}_{τ} , and there exists a weak limit $F \in \mathbb{H}^{\rho}_{\tau}$ such that $F^{(n)} \rightarrow F$. Moreover, $F \in \mathcal{S}^{\rho}$ because \mathcal{S}^{ρ} is closed. Therefore $Y_0 := \mathsf{L}_0(F)$ satisfies $\rho(Y_0) = 0$.

Since $F^{(n)}
ightharpoonup F$ in \mathbb{H}^{ρ}_{τ} and L_{0} is compact, we have $Y_{0}^{(n)}
ightharpoonup Y_{0}$ in $L^{2}(\rho)$. Therefore, $\rho \left((Y_{0})^{2} \right) = \lim_{n \to \infty} \rho \left((Y_{0}^{(n)})^{2} \right) = 1$. It remains to show that $\mathcal{E}^{\rho}(F) = c^{\rho}$. Since c^{ρ} is the infimum, $\mathcal{E}^{\rho}(F) \geq c^{\rho}$. It is noted that the map $F \mapsto \mathcal{E}^{\rho}(F)$ is convex. Therefore,

$$\mathcal{E}^{\rho}(F^{(n)}) \ge \mathcal{E}^{\rho}(F) + \langle \nabla \mathcal{E}^{\rho}(F), F^{(n)} - F \rangle$$

We have already shown that $\tilde{F} \mapsto \langle \nabla \mathcal{E}^{\rho}(F), \tilde{F} \rangle$ is a bounded linear functional. Therefore, letting $n \to \infty$, the second term on the right-hand side converges to zero and

$$\mathcal{E}^{\rho}(F) \leq \lim_{n \to \infty} \mathcal{E}^{\rho}(F^{(n)}) = c^{\rho}$$

D. Proof of Proposition 6

Proof: [of Prop. 6] Suppose any one of the three conditions hold. We claim then

(claim)
$$\mathcal{E}^{\rho}(F) = 0 \Longrightarrow \operatorname{var}^{\rho}(Y_0(X_0)) = 0$$

Supposing the claim is true, the proof is by contradiction. To see this suppose $c^{\rho} = 0$, then by Lemma 2 there exists $\mathcal{E}^{\rho}(F) = 0$ such that $\text{var}^{\rho}(Y_0(X_0)) = 1$ which contradicts the claim. It remains to prove the claim. For the three cases, the proof is described in the remainder of this appendix.

1. Ergodic case: At time t > 0, let ρ_t denote the probability law of X_t (without conditioning). Then $\rho \ll \rho_t$ and

 $\operatorname{supp}(\rho_t) =: \mathbb{S}'$ is identical for any t > 0. W.l.o.g., take \mathbb{S}' as the new state-space and consider the Markov process on \mathbb{S}' . Suppose $\mathcal{E}^{\rho}(F) = 0$. Then

$$\mathsf{E}^{\rho}\Big(\int_{0}^{\tau} \pi_{t}^{\rho}(\Gamma Y_{t}) \,\mathrm{d}t\Big) = 0 \implies \pi_{t}^{\rho}(\Gamma Y_{t}) = 0$$

almost every $t \in [0, \tau]$, $\mathsf{P}^{\rho}|_{\mathcal{Z}_{\tau}}$ -almost surely. For white noise observation model, $\operatorname{supp}(\pi_t^{\rho}) =: \mathbb{S}'$ and therefore $\Gamma Y_t(x) = 0$ for all $x \in \mathbb{S}'$, and therefore $\Gamma Y_t = 0$ with probability 1. If the model is ergodic, this implies Y_t is a constant function, and therefore $\mathsf{E}^{\rho}(\mathcal{V}_t^{\rho}(Y_t)) = 0$. The proof of the claim is completed by noting $\operatorname{var}^{\rho}(Y_0(X_0)) \leq \mathsf{E}^{\rho}(\mathcal{V}_t^{\rho}(Y_t))$ from (11b).

2. Observable case: The proof is based on using the equation for the conditional covariance $V_t^{\rho}(f, Y_t)$ stated below without proof:

$$d\mathcal{V}_{t}^{\rho}(f, Y_{t}) = \left(\pi_{t}^{\rho}(\Gamma(f, Y_{t})) + \mathcal{V}_{t}^{\rho}(\mathcal{A}f, Y_{t})\right)dt$$

$$+ \left(\mathcal{V}_{t}^{\rho}((f - \pi_{t}^{\rho}(f))(h - \pi_{t}^{\rho}(f)), Y_{t}) + \mathcal{V}_{t}^{\rho}(f, V_{t})\right)^{\mathsf{T}}dI_{t}^{\rho}$$
(16)

This equation is derived from the equation for the co-state (momentum) in the dual optimal control formulation of the nonlinear filter [3, Thm. 2]. Equation (16) is useful to prove the following Lemma which is the key to prove the claim.

Lemma 3: Suppose $\mathcal{E}^{\rho}(F) = 0$. Then for each $f \in \mathcal{O}$,

$$\mathcal{V}_t^{\rho}(f,Y_t) = 0$$
, P^{ρ} -a.s., a.e. $0 \le t \le \tau$

Proof: From the defining relation for $\mathcal{E}^{\rho}(F)$,

$$\pi_t^{\rho}(\Gamma Y_t) = 0, \ \mathcal{V}_t^{\rho}(h, Y_t) = 0, \ \mathcal{V}_t^{\rho}(V_t) = 0, \ \mathsf{P}^{\rho}$$
-a.s.

for a.e. $0 \le t \le \tau$. Using the Cauchy-Schwarz formula then for each $f \in C_b(\mathbb{S})$,

$$|\mathcal{V}^{\rho}_t(f,V_t)|^2 \leq \mathcal{V}^{\rho}_t(f)\mathcal{V}^{\rho}_t(V_t) = 0 \quad \mathsf{P}^{\rho}\text{-a.s.}$$

Similarly, upon using the Cauchy-Schwarz formula [1, Eq.1.4.3] for the carré du champ operator,

$$\pi_t^{\rho}(\Gamma(f,Y_t))=0$$
, P^{ρ} -a.s.

Based on these (16) simplifies to

$$d\mathcal{V}_{t}^{\rho}(f, Y_{t})$$

$$= \mathcal{V}_{t}^{\rho}(\mathcal{A}f, Y_{t}) dt + \left(\mathcal{V}_{t}^{\rho}(hf, Y_{t}) - \pi_{t}^{\rho}(h)\mathcal{V}_{t}^{\rho}(f, Y_{t})\right)^{\mathrm{T}} dI_{t}^{\rho}$$

Therefore.

$$\mathcal{V}_{t}^{\rho}(f, Y_{t}) = 0, \quad 0 \le t \le \tau$$

$$\Longrightarrow \quad \mathcal{V}_{t}^{\rho}(Af, Y_{t}) = 0, \quad \mathcal{V}_{t}^{\rho}(hf, Y_{t}) = 0, \quad 0 \le t \le \tau$$

Since $V_t^{\rho}(1,Y_t) = 0$ for all $t \in [0,\tau]$, the result follows from Defn. 4 of the observable space \mathcal{O} .

Based on the result in Lemma 3, if $\mathcal{O} = \mathbb{R}^d$, we again have $\mathsf{E}^\rho(\mathcal{V}_t^\rho(Y_t)) = 0$, and then the claim follows.

3. Detectable case: As shown in the ergodic case, if $\mathcal{E}^{\rho}(F) = 0$ then $\Gamma Y_t(x) = 0$ for all $x \in \mathbb{S}'$, and therefore $Y_t \in S_0$. If the system (\mathcal{A}, h) is detectable, then this implies $Y_t \in \mathcal{O}$ with probability 1. By Lemma 3, $\mathsf{E}^{\rho}(\mathcal{V}_t^{\rho}(Y_t)) = 0$ and the claim follows.

E. Proof of Proposition 7

Suppose the HMM (\mathcal{A},h) is not detectable. We wish to find $\rho \in \mathcal{P}(\mathbb{S}) \setminus \mathcal{N}$ and $F \in \mathbb{H}^{\rho}_{\tau}$ such that $\mathcal{E}^{\rho}(F) = 0$ and $\operatorname{var}^{\rho}(Y_0(X_0)) = 1$.

From the definition of detectability, there exists a function $f \in S_0$ that is not in \mathcal{O} . We pick $\rho \in \mathcal{P}(\mathbb{S})$ such that

- 1) $\rho(f) = 0$,
- 2) $\rho(f^2) > 0$,
- 3) $\rho(fg) = 0$ for all $g \in \mathcal{O}$.

We then claim that

(claim)
$$\pi_t^{\rho}(fg) = 0$$
, $\forall g \in \mathcal{O}, 0 \le t \le \tau$

Assuming the claim is true $\pi_{\tau}^{\rho}(f) = 0$ and therefore $f \in S_0$. Because $f \in S_0$, Af = 0 and therefore, $Y_t = f$ and $V_t = 0$ for all $0 \le t \le \tau$ solves the BSDE (12), and corresponding energy $\mathcal{E}^{\rho}(f) = 0$ and $\text{var}^{\rho}(Y_0(X_0)) = \rho(f^2) > 0$.

We now prove the claim. Since $f \in S_0$, Af = 0 and $\Gamma(f,g) = 0$ by Cauchy-Schwarz inequality, and consequently, A(fg) = fAg. From (6):

$$d\pi_t^{\rho}(fg) = \pi_t^{\rho}(f\mathcal{A}g)dt + \pi_t^{\rho}(ghf)^{\mathrm{T}}dI_t = 0$$

because $Ag \in \mathcal{O}$ and $gh \in \mathcal{O}$ by Defn. 4.
