
WeightedPose: Generalizable Cross-Pose Estimation via Weighted SVD

Xuxin Cheng, Heng Yu, Harry Zhang, Wenxing Deng
Course Project for VLR at CMU, Spring 2023

Abstract

We introduce a new approach for robotic manipulation tasks in human settings that necessitates understanding the 3D geometric connections between a pair of objects. Conventional end-to-end training approaches, which convert pixel observations directly into robot actions, often fail to effectively understand complex pose relationships and do not easily adapt to new object configurations. To overcome these issues, our method focuses on learning the 3D geometric relationships, particularly how critical parts of one object relate to those of another. We employ Weighted SVD in our standalone model to analyze pose relationships both in articulated parts and in free-floating objects. For instance, our model can comprehend the spatial relationship between an oven door and the oven body, as well as between a lasagna plate and the oven. By concentrating on the 3D geometric connections, our strategy empowers robots to carry out intricate manipulation tasks based on object-centric perspectives¹.

1 Introduction

Numerous robotic tasks involve relocating an object to a position relative to another object. For instance, a culinary robot might be required to put a lasagna in an oven, set a pot on a stove, place a dish in a microwave, position a mug on a rack, or situate a cup on a shelf. Mastery in positioning objects according to task-specific needs is crucial for robots working in human environments. Moreover, this capability should extend to new items within known categories, such as inserting different trays into an oven or different mugs onto a rack.

Traditionally in robot learning, policies are trained end2end to translate pixel data directly into robot actions. However, these end-to-end policies struggle with understanding intricate pose relationships like those mentioned and often fail to adapt to new object configurations. In response, we suggest a method that focuses on understanding the 3D geometric relationships between pairs of objects. For the aforementioned tasks, this involves discerning the spatial relationships between critical parts of one object in relation to another—for example, analyzing both the connection between an oven door and the main oven body and between a lasagna plate and the oven itself. Our proposed independent model uses Weighted SVD to analyze these pose relationships, whether they involve articulated parts or free-floating objects.

2 Background

Object Pose Estimation: Pose estimation involves detecting and determining the 6DoF (six degrees of freedom) pose of an object, which encompasses its position and orientation relative to a predefined object reference frame. Recent research has suggested using 3D semantic keypoints as a novel object representation form (19; 28; 36; 10; 11; 32). Recent work (20; 27; 33; 21) Although keypoint-based

¹<https://github.com/harryzhang0G/weighted-pose/tree/main>

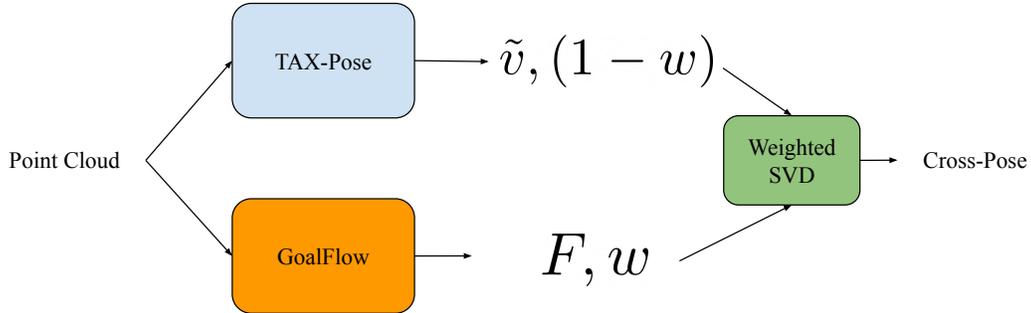

Figure 1: Unified Weighted Pose architecture. The model first takes as input a point cloud, and then learns to predict a weight for the point cloud. This weight is used in the downstream SVD module to combine the GoalFlow and TAX-Pose outputs.

methods show generalization within object classes, they rely heavily on extensive hand-annotated data or simulated environments to learn keypoint locations. In contrast, our method can learn from merely 10 real-world demonstrations. Another technique involves using dense embeddings, such as Dense Object Nets (DON) and Neural Descriptor Fields (NDF), which facilitate class-wide generalization by predicting and matching dense embeddings from observations to those of demonstration objects. In contrast, our method is able to learn from just 10 real-world demonstrations. Another approach is to use dense embeddings, such as Dense Object Nets (DON) (9) and Neural Descriptor Fields (NDF) (31; 7), which achieve generalization across classes by predicting dense embeddings in the observation and matching them to embeddings of the demonstration objects. However, both DON and NDF presuppose that the target object is manipulated relative to a static reference in a "known canonical configuration" (for example, the fixed pose of a mug rack in NDF). Unlike these methods, our approach understands the geometric relationships between pairs of objects, allowing it to function without assuming a static environment (31). In contrast, our method reasons about the geometric relationship between a pair of objects and hence does not need to assume a static environment.

Articulated Object Manipulation: The manipulation of articulated objects and those with non-rigid characteristics continues to be a challenging area of research, largely because of their intricate geometries and kinematics. Earlier research has suggested handling these objects using hand-crafted analytical methods, for example, by immobilizing a sequence of hinged objects through (5; 29; 1; 2; 39). Berenson et al. (3) proposed a planning framework for manipulation under kinematic constraints. Katz et al. (15) proposed an approach to acquire manipulation policies in real-world settings by using a relational representation that is grounded and learned through interaction. This method was enhanced by the creation of expansive datasets of articulated objects like the PartNet dataset Mo et al. (22) and Partnet-Mobility by Xiang et al. (35); Sim et al. (30); Jin et al. (14), several studies have suggested using learning techniques that combine large-scale simulation with supervised visual learning. Mo et al. (23) introduced an approach to develop articulation manipulation policies through extensive simulation and visual affordance learning. Xu et al. (37) suggested a framework that acquires knowledge of articulation affordances and includes an action scoring module, which is utilized to manipulate objects. Various studies have specifically concentrated on the visual identification and calculation of articulation parameters, developing methods to estimate the pose (42; 45; 43; 38; 34; 12; 16) and identify articulation parameters (13; 41; 44) to obtain action trajectories. Moreover, (24; 4; 6; 17; 18; 8) tackle the problem using statistical motion planning.

3 Method

We first slightly modify the FlowBot 3D training objective. Instead of defining an instantaneous motion vector field as the training data directly, we make the network learn to output a flow field to the completely open state directly. Since this version of FlowBot 3D learns to output a dense representation to the goal state directly, we call this model Goal Flow.

Formally, given a point cloud $\{\mathbf{p}_i\} \forall i \in \{1, \dots, N\}$ this Goal Flow model outputs a dense flow field $F \in \mathbb{R}^{N \times 3}$, where each flow vector $\delta_i \in \mathbb{R}^3$ in the F represents a goal flow vector such that

point $p_i + \delta_i$ is in the fully open goal state. Ideally, this model should be deployed exclusively for articulated objects in that Goal Flow was shown to achieve suboptimal performances in (25; 26).

To combine the Goal Flow model with TAX-Pose, we also make the Goal Flow network output an auxiliary weight $w \in \mathbb{R}$, which assigns weight w to Goal Flow and $1 - w$ to TAX-Pose.

For the TAX-Pose component of the Weighted Pose unified architecture, we do not make any significant modifications and ideally the TAX-Pose model should be deployed for free-floating objects exclusively.

In TAX-Pose, we have:

$$\mathcal{J}(\mathbf{T}_{AB}) = \sum_{i=1}^{N_A} \alpha_i^A \|\mathbf{T}_{AB} \mathbf{p}_i^A - \tilde{\mathbf{v}}_i^A\|_2^2 + \sum_{i=1}^{N_B} \alpha_i^B \|\mathbf{T}_{AB}^{-1} \mathbf{p}_i^B - \tilde{\mathbf{v}}_i^B\|_2^2,$$

where

$$\mathbf{A} = [\mathbf{P}_A^{*\top} \quad \tilde{\mathbf{V}}_B^{*\top}], \quad \mathbf{B} = [\tilde{\mathbf{V}}_A^{*\top} \quad \mathbf{P}_B^{*\top}]^\top, \quad \mathbf{\Gamma} = \text{diag}([\alpha_A \quad \alpha_B])$$

Now we want to add another term in the SVD step. Specifically, we want the network to learn which one of the two models, TAX-Pose and Goal-Flow, is more important based on point cloud observations. Thus, we want a SVD step that incorporates the TAX-Pose residual, weighted by $(1 - w)$ and Goal-Flow weighted by w . So the new SVD formulation becomes:

$$\begin{aligned} \mathcal{J}(\mathbf{T}_{AB}) = (1 - w) & \left[\sum_{i=1}^{N_A} \alpha_i^A \|\mathbf{T}_{AB} \mathbf{p}_i^A - \tilde{\mathbf{v}}_i^A\|_2^2 + \sum_{i=1}^{N_B} \alpha_i^B \|\mathbf{T}_{AB}^{-1} \mathbf{p}_i^B - \tilde{\mathbf{v}}_i^B\|_2^2 \right] \\ & + w \sum_{i=1}^{N_A} \|\mathbf{T}_{AB} \mathbf{p}_i^A - (\mathbf{p}_i^A + \delta_i^A)\|_2^2, \end{aligned}$$

where δ_i^A is the i -th point's goal flow. To make this approach viable we optimize R and t in \mathbf{T}_{AB} separately:

$$\begin{aligned} J = & \sum_i^{N_A} ((1 - w)\alpha_i \|\mathbf{R}\mathbf{p}_i^A + t - \tilde{\mathbf{v}}_i^A\|^2 + w\|\mathbf{R}\mathbf{p}_i^A + t - \mathbf{p}_i^A + \delta_i^A\|^2) \\ & + \sum_i^{N_B} (1 - w)\alpha_i \|R^{-1}\mathbf{p}_i^B - t - \tilde{\mathbf{v}}_i^B\|^2 \end{aligned}$$

We first solve for the optimal translation t^* :

$$\begin{aligned}
\frac{\partial J}{\partial t} &= 0 \\
&= \sum_i^{N_A} (2(1-w)\alpha_i (t + R\mathbf{p}_i^A - \tilde{\mathbf{v}}_i^A) + 2w (t + R\mathbf{p}_i^A - \mathbf{p}_i^A - \delta_i^A)) \\
&\quad + 2(1-w) \sum_i^{N_B} \alpha_i (R^{-1}\mathbf{p}_i^B - t - \tilde{\mathbf{v}}_i^B) \\
&= \sum_i^{N_A} ((2-2w)\alpha_i + 2w)t + ((2-2w)\alpha_i + 2w)R\mathbf{p}_i^A - 2w\delta_i^A - (2-2w)\alpha_i\tilde{\mathbf{v}}_i^A - 2w\mathbf{p}_i^A \\
&\quad + \sum_i^{N_B} -(2-2w)\alpha_i t + (2-2w)\alpha_i(R^{-1}\mathbf{p}_i^B - \tilde{\mathbf{v}}_i^B) \\
&= \left[\sum_i^{N_A} [(2-2w)\alpha_i + 2w] + \sum_i^{N_B} -(2-2w)\alpha_i \right] t \\
&\quad + \sum_i^{N_A} ((2-2w)\alpha_i + 2w)R\mathbf{p}_i^A - 2w\delta_i^A - (2-2w)\alpha_i\tilde{\mathbf{v}}_i^A - 2w\mathbf{p}_i^A \\
&\quad + \sum_i^{N_B} (2-2w)\alpha_i(R^{-1}\mathbf{p}_i^B - \tilde{\mathbf{v}}_i^B) \\
t^* &= - \left(\sum_i^{N_A} ((2-2w)\alpha_i + 2w)R\mathbf{p}_i^A - 2w\delta_i^A - (2-2w)\alpha_i\tilde{\mathbf{v}}_i^A - 2w\mathbf{p}_i^A \right. \\
&\quad \left. + \sum_i^{N_B} (2-2w)\alpha_i(R^{-1}\mathbf{p}_i^B - \tilde{\mathbf{v}}_i^B) \right) / \left[\sum_i^{N_A} [(2-2w)\alpha_i + 2w] + \sum_i^{N_B} -(2-2w)\alpha_i \right]
\end{aligned}$$

Further simplifying, we have:

$$\begin{aligned}
t^* &= \frac{(1-w) \sum_i^{N_A} \alpha_i^A (\tilde{\mathbf{v}}_i^A - R\mathbf{p}_i^A)}{(1-w) \sum_i^{N_A} \alpha_i^A + w \sum_i^{N_A} 1 + (1-w) \sum_i^{N_B} \alpha_i^B} \\
&\quad + \frac{w \sum_i^{N_A} (\mathbf{p}_i^A + \delta_i^A) - R\mathbf{p}_i^A}{(1-w) \sum_i^{N_A} \alpha_i^A + w \sum_i^{N_A} 1 + (1-w) \sum_i^{N_B} \alpha_i^B} \\
&\quad + \frac{(1-w) \sum_i^{N_B} \alpha_i^B (\tilde{\mathbf{v}}_i^B - R^{-1}\mathbf{p}_i^B)}{(1-w) \sum_i^{N_A} \alpha_i^A + w \sum_i^{N_A} 1 + (1-w) \sum_i^{N_B} \alpha_i^B}
\end{aligned}$$

Note here that we colorcode the expression here. Intuitively, the resulting translation is a weighted sum of three translation terms. The **red** color represents the action object's translation via TAX-Pose, the **blue** color represents the action object's translation via GoalFlow, and the **purple** color represents the anchor object's translation via TAX-Pose.

We can then construct the matrices as follows:

$$\mathbf{A} = [\mathbf{P}_A^\top \quad \tilde{\mathbf{V}}_B^\top \quad \mathbf{P}_A^\top], \quad \mathbf{B} = [\tilde{\mathbf{V}}_A^\top \quad \mathbf{P}_B^\top \quad \mathbf{P}_A^\top + \Delta_A]^\top$$

$$\mathbf{\Gamma} = \begin{bmatrix} (1-w) \cdot \alpha_A & 0 & 0 \\ 0 & (1-w) \cdot \alpha_B & 0 \\ 0 & 0 & w \end{bmatrix}$$

where Δ_A is the de-meanned goal flow field. Note here that everything here is **NOT** de-meanned.

We then solve for the SVD:

$$\mathbf{U}\mathbf{\Sigma}\mathbf{V}^\top = \text{svd}(\mathbf{A}\mathbf{\Gamma}\mathbf{B}^\top)$$

and then we solve for rotation matrix R . Plugging it back into the t^* equations we get t .

To train the WeightedPose, we use a set of losses defined below, which are similar to those in (25). We assume we have access to a set of demonstrations of the task, in which the action and anchor objects are in the target relative pose such that $\mathbf{T}_{AB} = \mathbf{I}$.

Point Displacement Loss:

Rather than directly supervising the rotation and translation (as seen in DCP), we manage the predicted transformation by observing its impact on the points. To do this, we utilize the point clouds from the objects in their demonstration setup and apply a random transformation to each cloud for this loss, $\hat{\mathbf{P}}_A = \mathbf{T}_\alpha \mathbf{P}_A$, and $\hat{\mathbf{P}}_B = \mathbf{T}_\beta \mathbf{P}_B$. This would give us a ground truth transform of $\mathbf{T}_{AB}^{GT} = \mathbf{T}_\beta \mathbf{T}_\alpha^{-1}$; the inverse of this transform would move object B to the correct position relative to object A . Using the actual transformation as a reference, we calculate the Mean Squared Error (MSE) loss by comparing the correctly transformed points to those transformed based on our predicted values.

$$\mathcal{L}_{\text{disp}} = \|\mathbf{T}_{AB} \mathbf{P}_A - \mathbf{T}_{AB}^{GT} \mathbf{P}_A\|^2 + \|\mathbf{T}_{AB}^{-1} \mathbf{P}_B - \mathbf{T}_{AB}^{GT^{-1}} \mathbf{P}_B\|^2 \quad (1)$$

Direct Correspondence Loss. Although the Point Displacement Loss accurately reflects errors observed during inference, it may result in correspondences that are individually inaccurate yet average out to the correct pose. To enhance these errors, we directly supervise the correspondences that are learned \tilde{V}_A and \tilde{V}_B :

$$\mathcal{L}_{\text{corr}} = \|\tilde{V}_A - \mathbf{T}_{AB}^{GT} \mathbf{P}_A\|^2 + \|\tilde{V}_B - \mathbf{T}_{AB}^{GT^{-1}} \mathbf{P}_B\|^2. \quad (2)$$

Correspondence Consistency Loss. Additionally, a consistency loss may be employed. This loss penalizes any discrepancies between correspondences and the final predicted transformation. An advantage of this loss is its ability to encourage the network to maintain object rigidity while it learns precise object placement. It is important to note that this is akin to the Direct Correspondence Loss, except that it relies on the predicted transformation rather than the ground truth. Therefore, this loss does not require any ground truth data:

$$\mathcal{L}_{\text{cons}} = \|\tilde{V}_A - \mathbf{T}_{AB} \mathbf{P}_A\|^2 + \|\tilde{V}_B - \mathbf{T}_{AB}^{-1} \mathbf{P}_B\|^2. \quad (3)$$

Direct SE(3) Transformation Loss. We also define a loss directly for the transformation outputted in $SE(3)$, supervising between the SVD output pose and ground-truth pose.

$$\mathcal{L}_{\text{tr}} = \|\mathbf{T}_{AB} - \mathbf{T}_{AB}^{GT}\|_F \quad (4)$$

4 Experiments

We describe a PartNet-Mobility Placement task as the act of positioning an action object in relation to an anchor object according to a predefined semantic goal position. This task demands that the model generate a cross-pose for both articulated parts and free-floating objects. We have chosen a collection of household furniture items from the PartNet-Mobility dataset for this purpose (35) and a set of small rigid objects released with the Ravens simulation environment (40). When the model is required to estimate goal pose for the articulated part, following the terminology in (25), articulated part serves as the action object, while the static body of the furniture acts as the anchor object. Conversely, when the model estimates the goal pose for free-floating objects, the scenario aligns with the same setting as previously discussed (25). We compare the proposed method to several baselines. First, we compare against TAX-Pose trained on both free-floating and articulated objects as well as Goal-Flow trained on both categories of objects. We then compare against an oracle model that classifies if the objects of interest are free-floating or articulated, and deploys the model accordingly.

We describe the baselines in details:

- Goal Flow Pretrained (GF Pretrained): Pretrain Goal Flow on articulated objects only and test on both articulated and free-floating objects.
- TAX-Pose Pretrained (TP Pretrained): Pretrain TAX-Pose on free-floating objects only and test on both articulated and free-floating objects.

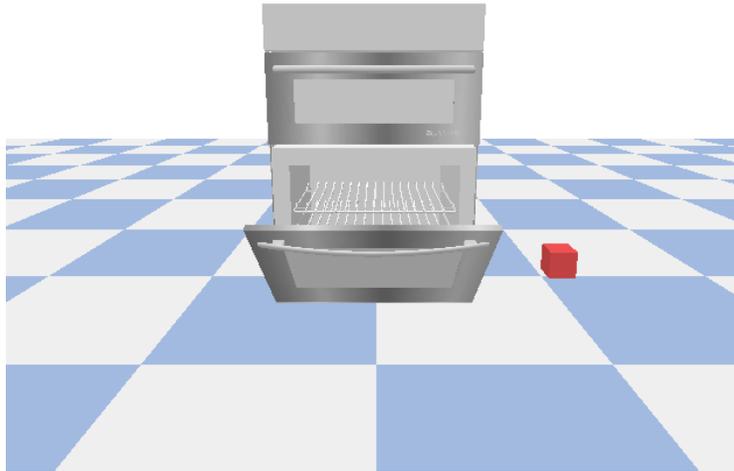

Figure 2: Task illustration. The model needs to first output goal pose for opening the oven door, and then output goal pose for putting the block inside the oven.

- Weighted Pose Original Loss (WP OG Loss): Weighted Pose trained and test on both free-floating and articulated objects using the original TAX-Pose loss.
- Weighted Pose Post-SVD Loss (WP Post-SVD): Weighted Pose trained and test on both free-floating and articulated objects but using the post-SVD TAX-Pose loss.
- Weighted Pose Post-SVD & Transformation Loss (WP Post-SVD): Weighted Pose trained and test on both free-floating and articulated objects but using both the post-SVD TAX-Pose loss and direct transformation loss. Where the transformation loss is the MSE between the predicted $SE(3)$ transformation and the ground-truth $SE(3)$ transformation.

We use the same PartNet-Mobility dataset as in TAX-Pose to evaluate the system. For semantic tasks, we will only select the “In” task as it is the most intuitive task. However, other than just performing evaluation on the free-floating objects, we will also evaluate the method on opening the articulate objects. Under this formulation, the action object is the articulated part and the anchor object is the static body. We will measure rotational error, translational error, and per-point MSE in our experiments. We follow the same train-val split as in TAX-Pose’s PartNet-Mobility dataset.

In Table 1, Goal Flow Pretrained baseline fails on free-floating objects and excels on articulated objects. Similarly for TAX-Pose pretrained, since it was trained on free-floating objects, it does do well on articulated objects, as the high rotational and translational errors indicate.

We next evaluate the variations of WeightedPose, which differ in the training paradigms. Using Weighted Pose Original Loss, which is trained using the original TAX-Pose loss, we are able to achieve better performance on both articulated and free-floating objects. Interestingly, the results we achieve using Weighted Pose Original Loss for articulated objects are better than the results from using Goal Flow pretrained on articulated objects.

While ideally, the w learned in this method should effectively act as a classifier of the input object (1 for articulated objects, 0 for free-floating objects). Intuitively, given a perfect w , the performance of WeightedPose would be upper-bounded by Goal Flow’s performance on articulated objects and by TAX-Pose on free-floating objects. However, a weighted combination of the two results due to the imperfect learned w weight could potentially correct the mistake made by each model by summing the results with a weighted sum. This may explain why WeightedPose sometimes performs better than its hypothesized upper bound on some objects.

Lastly, results suggest that the original loss used in TAX-Pose yields the best overall performance. However, it is worth noting that by using post-SVD loss during training, we are able to achieve lower

translational error in test time. Interestingly, by introducing a direct $SE(3)$ supervision, the results degrade marginally.

	Metrics	GF Pretrained		TP Pretrained		WP OG Loss		WP Post-SVD		WP Post SVD + T	
		FF	Art	FF	Art	FF	Art	FF	Art	FF	Art

Table 1: Weighted Pose Results: We compare Rotation Error, Translational Error, and Per-Point MSE for both training and validation objects.

5 Conclusions and Future Work

In conclusion, we have presented a method to combine the two architectures using weighted SVD. While this model is more of a proof-of-concept that attempts to unify the two architectures, it is worth pointing out that using the two models for the two categories of objects is able to help us generate goal poses for various free-floating and articulated objects. Moreover, by finetuning pretrained models from a weighted SVD combination, we are able to outperform the models on their respective training datasets categories. In future work, we wish to generalize the mathematics of the combined architecture beyond tasks that involve articulated and free-floating objects. We would also like to explore how such a unified architecture can aid motion planning as a geometric suggestor.
