# Inductive Reasoning with Equality Predicates, Contextual Rewriting and Variant-Based Simplification 

José Meseguer<br>Department of Computer Science<br>University of Illinois at Urbana-Champaign, USA<br>meseguer@illinois.edu

#### Abstract

An inductive inference system for proving validity of formulas in the initial algebra $T_{\mathcal{E}}$ of an order-sorted equational theory $\mathcal{E}$ is presented. It has 20 inference rules, but only 9 of them require user interaction; the remaining 11 can be automated as simplification rules. In this way, a substantial fraction of the proof effort can be automated. The inference rules are based on advanced equational reasoning techniques, including: equationally defined equality predicates, narrowing, constructor variant unification, variant satisfiability, order-sorted congruence closure, contextual rewriting, ordered rewriting, and recursive path orderings. All these techniques work modulo axioms $B$, for $B$ any combination of associativity and/or commutativity and/or identity axioms. Most of these inference rules have already been implemented in Maude's NuITP inductive theorem prover.

## 1 Introduction

In inductive theorem proving for equational specifications there is a tension between automated approaches, e.g., [58|28|39|41 [5|10|16|, and explicit induction ones, e.g., |42|30|34|14|27||5|38|36|31|. For two examples of automated equational inductive provers we can mention, among various others, Spike [10] and the superposition-based "inductionless induction" prover in [16]; and for explicit induction equational provers we can mention, again among various others, RRL [42], OBJ as a Theorem Prover [30|31], the OTS/CafeOBJ Method [25|60|27|26], and the Maude ITP [14|15|38|36]. The advantage of automated provers is that they do not need user interaction, although they often require proving auxiliary lemmas. Explicit induction is less automated, but it allows users to be "in the driver's seat" for finding a proof. This work presents an approach that combines features from automated and explicit-induction theorem proving in the context of proving validity in the initial algebra $T_{\mathcal{E}}$ of an order-sorted equational theory $\mathcal{E}$ for both arbitrary quantifier-free $(\mathrm{QF})$ formulas (expressed as conjunctions of clauses, some of which can be combined together as "multiclauses" in the sense explained in Section 3.1) and for existential formulas reduced to QF form by Skolemization (see Section 2.11).

The combination of proving styles is achieved by an inference system having 20 inference rules, where 11 of them are goal simplification rules that can be fully automated, whereas the remaining 9 require explicit user interaction, unless they are also automated by tactics. The simplification rules are powerful enough to be used on their own as an automatic (partial) oracle to answer inductive validity questions. For example, as mentioned in the earlier paper [49], a prototype version of a subset of the simplification rules made it possible to discharge a huge number of inductive validity verification conditions
(VCs) that were generated in the deductive verification proof in constructor-based reachability logic of the security properties of the IBOS Browser described in [69]68]. For a more recent example, the simplification rules implemented in the NuITP prover are invoked as an oracle to discharge VCs generated by the DM-Check tool when proving invariants of infinite-state systems [8].

The effectiveness of these simplification rules seems to be due to a novel combination of automatable equational reasoning techniques. Although several are well-known and some are widely used in superposition-based [6] automatic first-order theorem provers such as, e.g., [67|72], to the best of my knowledge they have not been previously combined for inductive theorem proving purposes with the extensiveness and generality presented here. They include: (1) equationally defined equality predicates [33]; (2) constrained narrowing [12]; (3) constructor variant unification [54|70]; (4) variant satisfiability [54|70]; (5) recursive path orderings [64|32]; (6) order-sorted congruence closure [53]; (7) contextual rewriting [73]; and (8) ordered rewriting, e.g., [47|4|59]). Furthermore, in this work all these techniques work modulo axioms $B$, for $B$ any combination of associativity and/or commutativity and/or identity axioms.

Since the paper [49] was published, two important developments have taken place. First, as further explained below, the inference system has been extended with new inference rules to make it more effective and scalable, and several of the rules in [49] have been extended in their scope and applicability for the same purpose. Furthermore, the mathematical foundations of the inference system have been developed and its completeness has been proved. Second, since mid 2021 to the present I have been working with Francisco Durán, Santiago Escobar and Julia Sapiña on the design and implementation of, and experimentation with, an inductive theorem prover for Maude equational programs called Maude's NuITP that implements (most of) the inference system presented in this paper and whose user manual, code and examples are publicly available [18]. The NuITP has been used in formal methods courses since 2022 at several universities, including the University of Illinois at Urbana-Champaign and the University of Málaga, and a substantial body of examples and applications have been developed. Furthermore, as already mentioned, the NuITP is used as a backend to dischage inductive verification conditions generated by the DM-Check tool [7|8], a deductive model checker under development by Kyungmin Bae, Santiago Escobar, Raúl López, José Meseguer and Julia Sapiña, which can be used to verify invariants of infinite-state concurrent systems. The theoretical and tool developments have been closely related. For example, based on the experience gained with the NuITP, two new rules have been added to the inference system to increase the effectiveness of the NuITP.

## Relationship of this Paper to an Earlier Conference Paper

In 2020 Stephen Skeirik and I published a preliminary set of inference rules and some preliminary experiments in the conference paper [49]. Since then, I have advanced the theoretical foundations and have improved and substantially extended the inference system presented in [49]. Also, as mentioned above, since mid 2021 these advances have been used both as the theoretical basis of Maude's NuITP tool and as a means to make the NuITP a more effective prover.

Besides making substantial improvements to the inference rules in [49] and developing new formula simplification techniques (see below), four new inference rules, namely, the
narrowing induction (NI), narrowing simplification (NS), equality (Eq) and cut (Cut) rules, make the inference system more powerful and versatile.

NI and NS both have the effect of fully evaluating at the symbolic level one step of computation with a defined function symbol $f$ for all the ground instances of a given expression $f(\vec{v})$ appearing in a conjecture. NI and NS complement each other and serve somewhat different purposes. NI is a full-blown induction rule that inducts on smaller calls to $f$ appearing in the righthand sides or conditions of the equations defining $f$. Instead, NS is used mainly for goal simplification purposes and is a key contributor to the "virtuous circle" of simplification by which "chain reactions" of formula simplification are triggered. As I show in several examples, NI compares favorably with more standard rules like structural induction or its more flexible generalization to generator set induction (the GSI rule in the present system). Another attractive feature of both the NI and NS rules is that both can be used in a fully automatic way. For NS this is to be expected, but for NI this opens up the future prospect of an automated use of the inference system where the NuITP could be used as a backend by many other formal tools. The Eq inference rule allows the application of a conditional equation, either in the original theory, an induction hypothesis, or an already proved lemma, to a subterm of the current goal with a user-provided (partial) substitution. The Cut rule has the usual meaning in many other inference systems. In the context of reasoning with multiclauses, which are conditional formulas of the form $\Gamma \rightarrow \Lambda$ with $\Gamma$ a conjunction of equalities (more on this in §3), it serves the purpose of a generalized modus ponens inference rule, since modus ponens becomes the special case when $\Gamma=\top$.

Another important new addition is the use of ordered rewriting modulo axioms $B-$ including conditional ordered rewriting - to substantially increase the possibility of applying induction hypotheses as rewrite rules for conjecture simplification. Two entirely new sections have been added on this topic (Sections 2.10 and 3.2), and a considerably more nuanced classification of different types of induction hypotheses is made in Section 3.1 in order to more effectively apply induction hypotheses to simplify conjectures. Furthermore, to boost the effectiveness of ordered rewriting for conjecture simplification purposes, Section 2.10 concludes with a new semantics for ordered rewriting that, by making ordered rewriting "background theory aware," is strictly more powerful in simplifying conjectures than the standard semantics of ordered rewriting. To the best of my knowledge this new semantics seems to be a novel contribution.

Four other entirely new sections have been added: Section 2.3 on rewriting logic; Section 2.9, explaining in detail some nuances about generator sets modulo axioms $B$ and all the technicalities about function subcalls needed to support the new NI rule described above; Section 2.11, explaining in detail the model-theoretic semantics of Skolemization for satisfaction of formulas existentially quantified on Skolem function symbols and constants, which supports a more general $\exists$ rule now included in the inference system to support inductive reasoning about quantified first-order formulas; and Section 5] illustrating the use of the inference system with a collection of examples (all new, except one borrowed from [49]) that go beyond the numerous other examples given in Section 4 to illustrate the use of individual rules, which are also new. The examples in Section 5 illustrate both the meaning and the application of important inference rules -including GSI, NI, LE, CAS, VA and Cut, and the new, generalized versions of EPS, CVUL and ICC - as well as the remarkable power and economy of thought of reasoning with the multiclause representation of formulas supported by the inference system, as opposed to the usual clause
representation. Last but not least, the proof of soundness of the inference system is given in Appendix B
Besides all these entirely new additions and inference rules, the following substantial extensions of previous inference rules further differentiate the current inference system from its erlier, preliminary version in [49]:

1. The equality predicate simplification rule (EPS) and the inductive congruence closure rule (ICC) have been substantially generalized to increase their effectiveness: they now can also use ordered rewriting to apply a much wider range of induction hypotheses in the simplification process that could not be applied in the previous formulations of EPS and ICC.
2. The two previous constructor variant unification left simplification rules, namely, CVUL and CVUFL, have been substantially generalized and subsumed by a single, more widely applicable CVUL rule.
3. The substitution left (SUBL) and right (SUBR) rules have also been substantially generalized: now they can, not only substitute equations of the form $x=u$ with $x$ a variable as before, but can also substitute equations of the form $\bar{x}=u$, with $\bar{x}$ a (universal) Skolem constant.
4. The generator set induction (GSI) rule now generates stronger induction hypotheses.
5. The case (CAS) rule has also been generalized, so that it can be applied, not just on a variable, but also on a (universal) Skolem constant.
6. The existential ( $\exists$ ), lemma enrichment (LE), split (SP) and variable abstraction (VA) rules have been substantially generalized.

## 2 Preliminaries

Since many different techniques are combined in the inductive inference system, to make the paper self-contained and as easy to understand as possible, an unusually long list of preliminaries need to be covered on: (i) order-sorted first-order logic, (ii) convergent theories and constructors; (iii) rewriting logic; (iv) narrowing; (v) equationally-defined equality predicates; (vi) congruence closure; (vii) contextual rewriting; (viii) variant unification and satisfiability; (ix) generating sets and function subcalls; (x) ordered rewriting; and (xi) Skolemization. Readers already familiar with some of these topics may skip the corresponding sections or, perhaps better, read them quickly to become familiar with the notation used.

### 2.1 Background on Order-Sorted First-Order Logic

Familiarity with the notions of an order-sorted signature $\Sigma$ on a poset of sorts ( $S, \leqslant$ ), an order-sorted $\Sigma$-algebra $A$, and the term $\Sigma$-algebras $T_{\Sigma}$ and $T_{\Sigma}(X)$ for $X$ an $S$-sorted set of variables is assumed, as well as with the notions of: (i) $\Sigma$-homomorphism $h: A \rightarrow B$ between $\Sigma$-algebras $A$ and $B$, so that $\Sigma$-algebras and $\Sigma$-homomorphisms form a category $\mathbf{O S A l g}_{\Sigma}$; (ii) order-sorted (i.e., sort-preserving) substitution $\theta$, its domain $\operatorname{dom}(\theta)$ and range $\operatorname{ran}(\theta)$, and its application $t \theta$ to a term $t$; (iii) preregular order-sorted signature $\Sigma$, i.e., a signature such that each term $t$ has a least sort, denoted $l s(t)$; (iv) the set $\widehat{S}=S /(\geqslant \cup \leqslant)^{+}$of connected components of a poset $(S, \leqslant)$ viewed as a DAG; and (v) for $A$ a $\Sigma$-algebra, the set $A_{s}$ of it elements of sort $s \in S$, and the set $A_{[s]}=\bigcup_{s^{\prime} \in[s]} A_{s^{\prime}}$ of all
elements in a connected component $[s] \in \widehat{S}$. It is furthermore assumed that all signatures $\Sigma$ have non-empty sorts, i.e., $T_{\Sigma, s} \neq \varnothing$ for each $s \in S$. All these notions are explained in detail in [51|29]. The material below is adapted from [54].

The first-order language of equational $\Sigma$-formulas is defined in the usual way: its atom $\square^{7}$ are $\Sigma$-equations $t=t^{\prime}$, where $t, t^{\prime} \in T_{\Sigma}(X)_{[s]}$ for some $[s] \in \widehat{S}$ and each $X_{s}$ is assumed countably infinite. The set $\operatorname{Form}(\Sigma)$ of equational $\Sigma$-formulas is then inductively built from atoms by: conjunction ( $\wedge$ ), disjunction ( $\vee$ ), negation $(\neg)$, and universal $\left(\forall x_{1}: s_{1}, \ldots, x_{n}: s_{n}\right)$ and existential ( $\left.\exists x_{1}: s_{1}, \ldots, x_{n}: s_{n}\right)$ quantification with distinct sorted variables $x_{1}: s_{1}, \ldots, x_{n}: s_{n}$, with $s_{1}, \ldots, s_{n} \in S$ (by convention, for $\varnothing$ the empty set of variables and $\varphi$ a formula, we define $(\forall \varnothing) \varphi \equiv(\exists \varnothing) \varphi \equiv \varphi$ ). A literal $\neg\left(t=t^{\prime}\right)$ is denoted $t \neq t^{\prime}$. Given a $\Sigma$-algebra $A$, a formula $\varphi \in \operatorname{Form}(\Sigma)$, and an assignment $\alpha \in[Y \rightarrow A]$, where $Y \supseteq \operatorname{fvars}(\varphi)$, with $\operatorname{fvars}(\varphi)$ the free variables of $\varphi$, the satisfaction relation $A, \alpha=\varphi$ is defined inductively as usual: for atoms, $A, \alpha=t=t^{\prime}$ iff $t \alpha=t^{\prime} \alpha$; for Boolean connectives it is the corresponding Boolean combination of the satisfaction relations for subformulas; and for quantifiers: $A, \alpha=\left(\forall x_{1}: s_{1}, \ldots, x_{n}: s_{n}\right) \varphi\left(\right.$ resp. $\left.A, \alpha \mid=\left(\exists x_{1}: s_{1}, \ldots, x_{n}: s_{n}\right) \varphi\right)$ holds iff for all $\left(a_{1}, \ldots, a_{n}\right) \in A_{s_{1}} \times \ldots \times A_{s_{n}}$ (resp. for some $\left.\left(a_{1}, \ldots, a_{n}\right) \in A_{s_{1}} \times \ldots \times A_{s_{n}}\right)$ we have $A, \alpha\left[x_{1}: s_{1}:=a_{1}, \ldots, x_{n}: s_{n}:=a_{n}\right] \models \varphi$, where if $\alpha \in[Y \rightarrow A]$, then $\alpha\left[x_{1}: s_{1}:=a_{1}, \ldots, x_{n}: s_{n}:=\right.$ $\left.a_{n}\right] \in\left[\left(Y \cup\left\{x_{1}: s_{1}, \ldots, x_{n}: s_{n}\right\}\right) \rightarrow A\right]$ and is such that for $y: s \in\left(Y \backslash\left\{x_{1}: s_{1}, \ldots, x_{n}: s_{n}\right\}\right), \alpha\left[x_{1}:\right.$ $\left.s_{1}:=a_{1}, \ldots, x_{n}: s_{n}:=a_{n}\right](y: s)=\alpha(y: s)$, and $\alpha\left[x_{1}: s_{1}:=a_{1}, \ldots, x_{n}: s_{n}:=a_{n}\right]\left(x_{i}: s_{i}\right)=a_{i}, 1 \leqslant$ $i \leqslant n . \varphi$ is called valid in $A($ resp. satisfiable in A) iff $A, \underline{\varnothing}=(\forall Y) \varphi($ resp. $A, \underline{\varnothing}=(\exists Y) \varphi)$, where $Y=\operatorname{fvars}(\varphi)$ and $\varnothing \in[\varnothing \rightarrow A]$ denotes the empty $S$-sorted assignment of values in $A$ to the empty $S$-sorted family $\varnothing$ of variables. The notation $A \models \varphi$ abbreviates validity of $\varphi$ in $A$. More generally, a set of formulas $\Gamma \subseteq \operatorname{Form}(\Sigma)$ is called valid in $A$, denoted $A \models \Gamma$, iff $A \models \varphi$ for each $\varphi \in \Gamma$. For a subsignature $\Omega \subseteq \Sigma$ and $A \in \mathbf{O S A l g}_{\Sigma}$, the reduct $\left.A\right|_{\Omega} \in \mathbf{O S A l g}_{\Omega}$ agrees with $A$ in the interpretation of all sorts and operations in $\Omega$ and discards everything in $\Sigma \backslash \Omega$. If $\varphi \in \operatorname{Form}(\Omega)$ we have the equivalence $A|=\varphi \Leftrightarrow A|_{\Omega}=\varphi$.

An OS equational theory is a pair $T=(\Sigma, E)$, with $E$ a set of (possibly conditional) $\Sigma$-equations. $\mathbf{O S A l g}_{(\Sigma, E)}$ denotes the full subcategory of $\mathbf{O S A l g}_{\Sigma}$ with objects those $A \in \mathbf{O S A l g}_{\Sigma}$ such that $A \models E$, called the $(\Sigma, E)$-algebras. $\mathbf{O S A l g}_{(\Sigma, E)}$ has an initial algebra $T_{\Sigma / E}$ [51]. Given $T=(\Sigma, E)$ and $\varphi \in \operatorname{Form}(\Sigma)$, we call $\varphi T$-valid, written $E \models \varphi$, iff $A \models \varphi$ for all $A \in \mathbf{O S A l g}_{(\Sigma, E)}$. We call $\varphi T$-satisfiable iff there exists $A \in \mathbf{O S A l g}_{(\Sigma, E)}$ with $\varphi$ satisfiable in A. Note that $\varphi$ is $T$-valid iff $\neg \varphi$ is $T$-unsatisfiable. The inference system in [51] is sound and complete for OS equational deduction, i.e., for any OS equational theory $(\Sigma, E)$, and $\Sigma$-equation $u=v$ we have an equivalence $E \vdash u=v \Leftrightarrow E \models u=v$. Deducibility $E \vdash u=v$ is abbreviated as $u=_{E} v$, called $E$-equality. An E-unifier of a system of $\Sigma$-equations, i.e., of a conjunction $\phi=u_{1}=v_{1} \wedge \ldots \wedge u_{n}=v_{n}$ of $\Sigma$-equations, is a substitution $\sigma$ such that $u_{i} \sigma={ }_{E} v_{i} \sigma, 1 \leqslant i \leqslant n$. An $E$-unification algorithm for $(\Sigma, E)$ is an algorithm generating a complete set of $E$-unifiers $\operatorname{Unif}_{E}(\phi)$ for any system of $\Sigma$ equations $\phi$, where "complete" means that for any $E$-unifier $\sigma$ of $\phi$ there is a $\tau \in \operatorname{Unif}_{E}(\phi)$ and a substitution $\rho$ such that $\sigma=\left._{E}(\tau \rho)\right|_{\operatorname{dom}(\sigma) \cup d o m(\tau)}$, where $=_{E}$ here means that for any variable $x$ we have $x \sigma=\left.{ }_{E} x(\tau \rho)\right|_{\operatorname{dom}(\sigma) \cup \operatorname{dom}(\tau)}$. The algorithm is finitary if it always terminates with a finite set $\operatorname{Unif}_{E}(\phi)$ for any $\phi$.

[^0]Given a set of equations $B$ used for deduction modulo $B$, a preregular OS signature $\Sigma$ is called $B$-preregula $\|^{2}$ iff for each $u=v \in B$ and substitutions $\rho, l s(u \rho)=l s(v \rho)$.

### 2.2 Background on Convergent Theories and Constructors

Given an order-sorted equational theory $\mathcal{E}=(\Sigma, E \cup B)$, where $B$ is a collection of associativity and/or commutativity and/or identity axioms and $\Sigma$ is $B$-preregular, we can associate to it a corresponding rewrite theory $[50] \overrightarrow{\mathcal{E}}=(\Sigma, B, \vec{E})$ by orienting the equations $E$ as left-to right rewrite rules. That is, each $(u=v) \in E$ is transformed into a rewrite rule $u \rightarrow v$. For simplicity I recall here the case of unconditional equations; for how conditional equations (whose conditions are conjunctions of equalities) are likewise transformed into conditional rewrite rules see, e.g., [45]. The main purpose of the rewrite theory $\overrightarrow{\mathcal{E}}$ is to make equational logic efficiently computable by reducing the complex bidirectional reasoning with equations to the much simpler unidirectional reasoning with rules under suitable assumptions. I assume familiarity with the notion of subterm $\left.t\right|_{p}$ of $t$ at a term position $p$ and of term replacement $t[w]_{p}$ of $\left.t\right|_{p}$ by $w$ at position $p$ (see, e.g., [17]). The rewrite relation $t \rightarrow{ }_{\vec{E}, B} t^{\prime}$ holds iff there is a subterm $\left.t\right|_{p}$ of $t$, a rule $(u \rightarrow v) \in \vec{E}$ and a substitution $\theta$ such that $u \theta=\left.{ }_{B} t\right|_{p}$, and $t^{\prime}=t[v \theta]_{p} . \rightarrow_{\vec{E}, B}^{*}$ denotes the reflexive-transitive closure of $\rightarrow \vec{E}_{E, B}$. The requirements on $\overrightarrow{\mathcal{E}}$ that allow reducing equational reasoning to rewriting are the following: (i) $\operatorname{vars}(v) \subseteq \operatorname{vars}(u)$; (ii) sort-decreasingness: for each substitution $\theta$ we must have $l s(u \theta) \geqslant l s(v \theta)$; (iii) strict $B$-coherence: if $t_{1} \rightarrow_{\vec{E}, B} t_{1}^{\prime}$ and $t_{1}={ }_{B} t_{2}$ then there exists $t_{2} \rightarrow \vec{E}, B t_{2}^{\prime}$ with $t_{1}^{\prime}={ }_{B} t_{2}^{\prime}$; (iv) confluence (resp. ground confluence) modulo $B$ : for each term $t$ (resp. ground term $t$ ) if $t \rightarrow_{\vec{E}, B}^{*} v_{1}$ and $t \rightarrow_{\vec{E}, B}^{*} v_{2}$, then there exist rewrite sequences $v_{1} \rightarrow \underset{\vec{E}, B}{*} w_{1}$ and $v_{2} \rightarrow_{\vec{E}, B}^{*} w_{2}$ such that $w_{1}={ }_{B} w_{2} ;$ (v) termination: the relation $\rightarrow{ }_{\vec{E}, B}$ is wellfounded (for $\vec{E}$ conditional, we require operational termination [45]). If $\overrightarrow{\mathcal{E}}$ satisfies conditions (i)-(v) (resp. the same, but (iv) weakened to ground confluence modulo $B$ ), then it is called convergent (resp. ground convergent). The key point is that then, given a term (resp. ground term) $t$, all terminating rewrite sequences $t \rightarrow_{\vec{E}, B}^{*} w$ end in a term $w$, denoted $t!_{\overrightarrow{\mathcal{E}}}$, that is unique up to $B$-equality, and it is called $t$ 's canonical form. Three major results then follow for the ground convergent case: (1) for any ground terms $t, t^{\prime}$ we have $t={ }_{E \cup B} t^{\prime}$ iff $t!_{\overrightarrow{\mathcal{E}}}={ }_{B} t^{\prime}!_{\overrightarrow{\mathcal{E}}}$, (2) the $B$-equivalence classes of canonical forms are the elements of the canonical term algebra $C_{\Sigma / E, B}$, where for each $f: s_{1} \ldots s_{n} \rightarrow s$ in $\Sigma$ and $B$-equivalence classes of canonical terms $\left[t_{1}\right], \ldots,\left[t_{n}\right]$ with $l s\left(t_{i}\right) \leqslant s_{i}$ the operation $f_{C_{\mathcal{E / E , B}}}$ is defined by the identity: $f_{C_{\Sigma / E, B}}\left(\left[t_{1}\right] \ldots\left[t_{n}\right]\right)=\left[f\left(t_{1} \ldots t_{n}\right)!_{\tilde{\mathcal{E}}}\right]$, and (3) we have an isomorphism $T_{\mathcal{E}} \cong C_{\Sigma / E, B}$.

A ground convergent rewrite theory $\overrightarrow{\mathcal{E}}=(\Sigma, B, \vec{E})$ is called sufficiently complete with respect to a subsignature $\Omega$, whose operators are then called constructors, iff for each ground $\Sigma$-term $t, t!_{\overrightarrow{\mathcal{E}}} \in T_{\Omega}$. Furthermore, for $\overrightarrow{\mathcal{E}}=(\Sigma, B, \vec{E})$ sufficiently complete w.r.t. $\Omega$, a ground convergent rewrite subtheory $\left(\Omega, B_{\Omega}, \vec{E}_{\Omega}\right) \subseteq(\Sigma, B, \vec{E})$ is called a constructor subspecification iff $\left.T_{\mathcal{E}}\right|_{\Omega} \cong T_{\Omega / E_{\Omega} \cup B_{\Omega}}$. If $E_{\Omega}=\varnothing$, then $\Omega$ is called a signature of free constructors modulo axioms $B_{\Omega}$.

[^1]
### 2.3 Background on Rewriting Logic

Convergent rewrite theories are ideal to specify deterministic systems, where computations have a unique final result. To formally specify non-deterministic and possibly concurrent systems, rewriting logic [50|52] is a suitable framework that contains convergent rewrite theories as a special case. A rewrite theory is a triple $\mathcal{R}=(\Sigma, E \cup B, R)$, where $(\Sigma, E \cup B)$ is an equational theory, and $R$ is a collection of, possibly conditional, rewrite rules. The intended meaning of $\mathcal{R}$ is to specify a system whose states are elements of the initial algebra $T_{\Sigma / E \cup B}$, and whose non-deterministic transitions are specified by the rules $R$.

Since the states are $E \cup B$-equivalence classes, conceptually, rewriting with $\mathcal{R}$ is rewriting modulo $E \cup B$, i.e., the relation $\rightarrow_{R / E \cup B}$. However, $\rightarrow_{R / E \cup B}$ is a hard to implement, complicated relation. In practice, the effect of rewriting with $\rightarrow_{R / E \cup B}$ is achieved by a much simpler relation $\rightarrow_{R: E, B}$ under the assumptions that: (i) $\vec{E}$ is convergent modulo $B$, and (ii) the rules $R$ are "coherent" with $\vec{E}$ modulo $B[71 \mid 22] . \rightarrow_{R: E, B}$ is the composed relation $\rightarrow_{R: E, B}=\rightarrow_{\vec{E}, B}!; \rightarrow_{R, B} ; \rightarrow_{\vec{E}, B}!$. One can think of $\rightarrow_{R: E, B}$ as executing the relation $\rightarrow_{R, B} \cup \rightarrow_{\vec{E}, B}$ with an eager strategy for $\rightarrow_{\vec{E}, B}$.

In this paper, the state transitions that we will be interested in will be deduction steps in inductive reasoning, so that the "states" are formulas in a deductive proof. Two different kinds of rewrite theories will be particularly useful for this purpose.

First, we will use object-level rewrite theories associated to specific inductive goals stating some property of the initial algebra $T_{\Sigma / E \cup B}$ of an equational theory $(\Sigma, E \cup B)$. These theories will be of the general form $\mathcal{R}=(\Sigma, E \cup B, H)$, where $H$ are the induction hypotheses associated to the goal we want to prove, used as rewrite rules. In their simplest form, hypotheses in $H$ may be equations or conditional equations. So, why not using instead the equational theory $(\Sigma, E \cup H \cup B)$ ? The key reason is that the equations $E$ will always be assumed to be ground convergent modulo $B$ when oriented as rules $\vec{E}$, but in general the rules $H$ need not be convergent. Nevertheless, as discussed in Section 3.2, they may be oriented in a manner ensuring their termination. The key advantage of the rewrite theory $\mathcal{R}=(\Sigma, E \cup B, H)$ versus the equational theory $(\Sigma, E \cup H \cup B)$, is that $\mathcal{R}$, by sharply distinguishing between $E$ and $H$, can consider a variety of non-deterministic ways in which the induction hypotheses $H$ can be applied. This is important for inductive theorem proving, because: (i) in a terminating rewrite theory, there is in general no such thing as the normal form of a term; in general there will be a set of such normal forms; and (ii) in fact, the signature $\Sigma$ that will be used will not be that of the given equational theory $\Sigma$, but, as explained in Section 2.5, its extension to a signature $\Sigma^{=}$whose terms denote quantifier-free $\Sigma$-formulas. That is, $\mathcal{R}$ will not be rewriting $\Sigma$-terms, but $\Sigma$-formulas, and it may very well be, that one of the normal forms of the goal formula $\varphi$ we are rewriting is $T$, so that the goal is proved, while another normal form $\varphi^{\prime}$ has only made partial progress towards proving $\varphi$. By considering the various ways in which the induction hypotheses $H$ can be applied, we maximize the chances of success in proving $\varphi$.

There is, however, a second way in which rewriting logic will play an important role in this work at the meta-level. The point is that rewriting logic is a flexible logical framework in which many other logics can be naturally represented [46|52]. In such representations, an inference rule in a given logic $\mathcal{L}$ becomes a possibly conditional rewrite rule. In particular, the inference rules in the inductive inference system presented in Section 4 will be the rewrite rules of a meta-level rewrite theory. Why meta-level? Because such inference rules are parametric on the given equational theory $(\Sigma, E \cup B)$ we are reasoning on
and, furthermore, may transform $(\Sigma, E \cup B)$ into another theory by adding, for example, induction hypotheses to a new goal. This is not just a theoretically pleasing way to think about the inductive inference system of Section 4 , but an eminently practical way to implement such an inference system in Maude using Maude's efficient support of meta-level reasoning through its META-LEVEL module. Most of the inference rules in this paper have already been implemented in Maude's NuITP in exactly this way.

### 2.4 Narrowing in a Nutshell

Narrowing modulo axioms $B$ generalizes rewriting modulo $B$ in the following, natural way. When we rewrite a term $t$ at position $p$ with a rule $l \rightarrow r$, the subterm $\left.t\right|_{p}$ matches modulo $B$ the lefthand side $l$. Instead, when we narrow a term $t$ at position $p$ with a rule $l \rightarrow r$ in $\vec{E}$, the subterm $\left.t\right|_{p}$ unifies modulo $B$ with the lefthand side $l$, a more general notion which allows us to symbolically evaluate the term $t$ with the given oriented equations $\vec{E}$. That is, "narrowing" is just technical jargon for symbolic evaluation with equations. Here is the precise definition: Given a ground convergent theory $\overrightarrow{\mathcal{E}}=(\Sigma, B, \vec{E})$, the narrowing relation $t \sim{ }_{\vec{E}, B}^{\alpha} u$ holds between $\Sigma$-terms $t$ and $u$ iff there is a non-variable position $p$ in $t$, a rule $l \rightarrow r$ in $\vec{E}$, and a $B$-unifier $\alpha$ of the equation $\left.t\right|_{p}=l$ such that $u=\left(t[r]_{p}\right) \alpha$, where we assume that the variables of $l \rightarrow r$ have been renamed if necessary so that no variables are shared with those of $t$. Since in this work we will consider ground convergent rewrite theories that are sufficiently complete with respect to free constructors modulo axioms $B_{\Omega} \subseteq B$, we can discuss a key property of narrowing, called "lifting," in this specific setting. For any non-constructor $\Sigma$ term $t$ and ground constructor substitution $\rho$, the ground term $t \rho$ can always be rewritten in one step to, say, $t \rho \rightarrow_{\vec{E}, B} v$. But any such rewriting computation is covered as an instance by a corresponding narrowing step $t \sim{ }_{\vec{E}, B}^{\alpha} u$, in the sense that there is a ground constructor substitution $\mu$ such that $u \mu={ }_{B} v$.

Note that there may be infinitely many such $\rho$ 's instantiating $t$, and therefore infinitely many one-step rewrites $t \rho \rightarrow{ }_{\vec{E}, B} v$, but all of them are simultaneously covered as instances by a finite number of one-step narrowing computations from $t$ of the form $t \overbrace{\vec{E}, B}^{\alpha} u$, assuming that: (i) $B$ has a finitary unification algorithm; and (ii) $\vec{E}$ is a finite set. As we shall see in Section 4 the NS and NI inference rules exploit this lifting property of narrowing for inductive reasoning purposes. More precisely, they do so using so-called constrained narrowing with possibly conditional rules $\vec{E}$, in the sense of [12].

### 2.5 Equationally Defined Equality Predicates in a Nutshell

Equationally-defined equality predicates [33] achieve a remarkable feat for QF formulas in initial algebras under reasonable executability conditions: they reduce first-order logic satisfaction of QF formulas in an initial algebra $T_{\mathcal{E}}$ to purely equational reasoning. This is achieved by a theory transformation ${ }^{3} \mathcal{E} \mapsto \mathcal{E}^{=}$such that, provided: (i) $\mathcal{E}=(\Sigma, E \cup B)$, with $B$ any combination of associativity and/or commutativity axioms, is ground convergent and operationally terminating modulo $B$, and is sufficiently complete with respect

[^2]to a subsignature $\Omega$ of constructors such that $\left.T_{\mathcal{E}}\right|_{\Omega} \cong T_{\Omega / B_{\Omega}}$, with $B_{\Omega} \subseteq B$, then: (ii) $\mathcal{E}^{=}$ is ground convergent operationally terminating and sufficiently complete and protects $\frac{4}{}$ both $\mathcal{E}$ and a new copy of the Booleans, of sort NewBool, where true and false are respectively denoted $\top, \perp$, conjunction and disjunction are respectively denoted $\wedge, \vee$, negation is denoted $\neg$, and a QF $\Sigma$-formula $\varphi$ is a term of sort NewBool. Furthermore, for any ground QF $\Sigma$-formulas $\varphi, \psi$ we have:
$$
T_{\mathcal{E}}=\varphi \quad \text { iff } \quad \varphi!\overrightarrow{\mathcal{E}}=\mathrm{T} .
$$
and, in particular,
$$
T_{\mathcal{E}}=\varphi \Leftrightarrow \psi \text { iff }(\varphi \Leftrightarrow \psi)!_{\overrightarrow{\mathcal{E}}}=\top \quad \text { iff } \quad T_{\mathcal{E}}=\mid=\varphi=\psi
$$
where $\varphi=\psi$ is an equality of Boolean terms of sort NewBool. Therefore, one can decide both the validity and the semantic equivalence of ground $\mathrm{QF} \Sigma$-formulas in $T_{\mathcal{E}}$ by reducing them to canonical form with the ground convergent rules in $\overrightarrow{\mathcal{E}}=$. In particular, and this is a property that will be systematically exploited in Section 4 for any QF $\Sigma$-formula $\varphi$, possibly with variables, we have $T_{\mathcal{E}} \mid=\varphi \Leftrightarrow\left(\varphi!_{\mathcal{E}}\right)$, where $\varphi!_{\mathcal{\mathcal { E }}}=$ may be a much simpler formula, sometimes just $\top$ or $\perp$. Since the $\mathcal{E} \mapsto \mathcal{E}^{-}$transformation excludes identity axioms from $\mathcal{E}$, one lingering doubt is what to do when $\mathcal{E}$ has also identity axioms $U$. The answer is that we can use the semantics-preserving theory transformation $\mathcal{E} \mapsto \mathcal{E}_{U}$ defined in [21], which turns identity axioms $U$ into rules $\vec{U}$ and preserves ground convergence, to reduce to the case $U=\varnothing$, provided we have $\left.T_{\mathcal{E}_{U}}\right|_{\Omega} \cong T_{\Omega / B_{\Omega}}$.

Since the rewrite theory $\overrightarrow{\mathcal{E}}_{U}^{=}$will be a key workhorse for the simplification rules described in Section 4 let us describe it in more detail, as well as the above-mentioned $\overrightarrow{\mathcal{E}} \mapsto \overrightarrow{\mathcal{E}}_{U}$ transformation with which the $\overrightarrow{\mathcal{E}} \mapsto \overrightarrow{\mathcal{E}}^{=}$transformation is composed. That is, let us look in more detail at the composition of transformations:

$$
\overrightarrow{\mathcal{E}} \mapsto \overrightarrow{\mathcal{E}}_{U} \mapsto \overrightarrow{\mathcal{E}}_{U}^{=} .
$$

The rewrite theory $\overrightarrow{\mathcal{E}}_{U}$ is defined as follows. $\mathcal{E}$ 's axioms $B$ can be decomposed as $B=$ $B_{0} \cup U$, where $U$ are the unit axioms, and $B_{0}$ are the remaining associative and/or commutative axioms. Then, $\overrightarrow{\mathcal{E}}_{U}=\left(\Sigma, B_{0}, \vec{E}_{U} \cup \vec{U}\right)$ is the semantically equivalent rewrite theory obtained from $\overrightarrow{\mathcal{E}}=(\Sigma, B, \vec{E})$ by: (i) adding the axioms $U$ as rules $\vec{U}$; and (ii) transforming the rules $\vec{E}$ into $\vec{E}_{U}$ by mapping each rule $(l \rightarrow r) \in \vec{E}$ to the set of rules $\left\{l_{i} \rightarrow r \alpha_{i} \mid 1 \leqslant i \leqslant n\right\}$, where $\left\{\left(l_{i}, \alpha_{i}\right)\right\}_{1 \leqslant i \leqslant n}$ is the finite set of $\vec{U}, B_{0}$-variants of $l$ (the notion of variant is explained in Section 2.8). For example, if _,_ is an ACU multiset union operator of sort MSet with identity $\varnothing$ and with subsort Elt of elements, a membership rewrite rule $x \in x, S \rightarrow$ true modulo ACU with $x$ of sort Elt and $S$ of sort MSet is mapped to the set of rules $\{x \in x \rightarrow$ true, $x \in x, S \rightarrow$ true $\}$ modulo AC. Since these theories are semantically equivalent, we have $T_{\mathcal{E}} \cong T_{\mathcal{E}_{U}}$. The second step $\overrightarrow{\mathcal{E}}_{U} \mapsto \overrightarrow{\mathcal{E}}_{U}^{=}$then adds the equationallydefined equality predicates to $\overrightarrow{\mathcal{E}}_{U}$ in the usual manner specified in [33]. The easiest equality predicate defining equations to illustrate are those for free constructors. For example, for the naturals in Peano notation they are: $(n=n)=$ true, $(s(n)=s(m))=(n=m)$, and $(s(n)=0)=$ false $\left({ }^{\prime}=\_\right.$is declared as a commutative operator of (fresh) sort NewBool $)$.

### 2.6 Order-Sorted Congruence Closure in a Nutshell

Let $(\Sigma, B)$ be an order-sorted theory where the axioms $B$ are only associativity-commutativity (AC) axioms and $\Sigma$ is $B$-preregular. Now let $\Gamma$ be a set of ground $\Sigma$-equations. The ques-

[^3]tion is: is $B \cup \Gamma$-equality decidable? (when $\Sigma$ has just a binary AC operator, this is called the "word problem for commutative semigroups"). The answer, provided in [53], is yes! We can perform a ground Knuth-Bendix completion of $\Gamma$ into an equivalent (modulo $B$ ) set of ground rewrite rules $c c_{B}^{>}(\Gamma)$ that is convergent modulo $B$, so that $t={ }_{B \cup \Gamma} t^{\prime}$ iff $t!_{\overrightarrow{\mathcal{E}}_{c c_{B}^{>}(I)}}=B^{\square} t^{\prime}!_{\overrightarrow{\mathcal{E}}_{c c_{B}^{\succ}(I)}}$, where $\overrightarrow{\mathcal{E}}_{c c_{B}^{>}(\Gamma)}$ is the rewrite theory $\overrightarrow{\mathcal{E}}_{c c_{B}^{>}(\Gamma)}=\left(\Sigma^{\square}, B^{\square}, c c_{B}^{>}(\Gamma)\right)$, with $\Sigma^{\square}$ the "kind completion" of $\Sigma$, which is automatically computed by Maude by adding a so-called "kind" sort $\top_{[s]}$ above each connected component $[s] \in \widehat{S}$ of ( $S, \leqslant$ ) and lifting each operation $f: s_{1} \cdots s_{n} \rightarrow s$ to its kinded version $f: \top_{\left[s_{1}\right]} \cdots \top_{\left[s_{n}\right]} \rightarrow \top_{[s]}$, and where $B^{\square}$ is obtained from $B$ by replacing each variable of sort $s$ in $B$ by a corresponding variable of sort $\mathrm{T}_{[s]}$. The symbol $>$ in $c c_{B}^{>}(\Gamma)$ is a total well-founded order on ground terms modulo $B$ that is used to orient the equations into rules. In all our uses $>$ will be an AC recursive path order $(\mathrm{RPO} \sqrt{5}$ based on a total order on function symbols [66]. The need to extend $\Sigma$ to $\Sigma^{\square}$ is due to the fact that some terms in $c c_{B}^{>}(\Gamma)$ may be $\Sigma^{\square}$-terms that fail to be $\Sigma$-terms.

Extending the above congruence closure framework from $A C$ axioms to axioms $B$ that contain any combination of associativity and/or commutativity axioms is quite smooth, but requires a crucial caveat: if some operator $f \in \Sigma$ is only associative, then $c c_{B}^{>}(\Gamma)$ may be an infinite set that cannot be computed in practice. This is due to the undecidability of the "word problem for semigroups." The Maude implementation of $c c_{B}^{>}(\Gamma)$ used in the NuITP supports this more general combination of axioms $B$; but when some $f \in \Sigma$ that is only associative appears somewhere in $\Gamma$, a bound is imposed on the number of iterations of the ground completion cycle. This means that, if the completion process has not terminated before the bound is reached, the above decidability result does not hold. However, for inductive simplification purposes it is enough to obtain a set of ground rules $c c_{B}^{>}(\Gamma)$ that is guaranteed to be terminating modulo $B$, and that, thanks to the, perhaps partial, completion, "approximates convergence" much better than the original $\Gamma$.

### 2.7 Contextual Rewriting in a Nutshell

Let $(\Sigma, B)$ be an order-sorted theory where the axioms $B$ contain any combination of associativity and/or commutativity axioms. What can we do to prove that in $(\Sigma, B)$ an implication of the form $\Gamma \rightarrow u=v$, with variables $\operatorname{vars}(\Gamma \rightarrow u=v)=X$ and $\Gamma$ a conjunction of equations, is valid? We can: (i) add to $\Sigma$ a set of fresh new constants $\bar{X}$ obtained from $X$ by changing each $x \in X$ into a constant $\bar{x} \in \bar{X}$ of same sort as $x$, (ii) replace the conjunction $\Gamma$ by the ground conjunction $\bar{\Gamma}$ obtained by replacing each $x \in X$ in $\Gamma$ by its corresponding $\bar{x} \in \bar{X}$, and obtaining likewise the ground equation $\bar{u}=\bar{v}$. By the Lemma of Constants and the Deduction Theorem we have [51]:

$$
(\Sigma, B) \vdash \Gamma \rightarrow u=v \Leftrightarrow(\Sigma(\bar{X}), \cup B \cup\{\bar{\Gamma}\}) \vdash \bar{u}=\bar{v}
$$

where $\Sigma(\bar{X})$ is obtained from $\Sigma$ by adding the fresh new constants $\bar{X}$, and $\{\bar{\Gamma}\}$ denotes the set of ground equations associated to the conjunction $\bar{\Gamma}$. But, disregarding the difference between $\bar{\Gamma}$ and $\{\bar{\Gamma}\}$, and realizing that $c c_{B}^{\succ}(\bar{\Gamma})$ is equivalent modulo $B^{\square}$ to $\bar{\Gamma}$, if we can prove $\bar{u}!_{\vec{\varepsilon}_{c c_{B}}(\bar{T})}={ }_{B^{\square}} \bar{v}!_{\vec{\varepsilon}_{c c_{B}}(\bar{T})}$, then we have proved $(\Sigma(\bar{X}), \cup B \cup\{\bar{\Gamma}\}) \vdash \bar{u}=\bar{v}$ and therefore $(\Sigma, B) \vdash \Gamma \rightarrow u=v$, where $\overrightarrow{\mathcal{E}}_{c c_{B}^{>}(\bar{\Gamma})}=\left(\Sigma(\bar{X})^{\square}, B^{\square}, c c_{B}^{>}(\bar{\Gamma})\right)$. Furthermore, if $\overrightarrow{\mathcal{E}}_{c c_{B}^{>}(\bar{\Gamma})}$ is

[^4]convergent (this may only fail to be the case if some $f \in \Sigma$ is associative but not commutative) this is an equivalence: $(\Sigma, B) \vdash \Gamma \rightarrow u=v$ iff $\bar{u}!_{\vec{\varepsilon}_{c c_{B}(\bar{T})}}={ }_{B} \overline{\bar{v}}!_{\vec{\varepsilon}_{\left.c c_{B} \overline{(T}\right)}}$, and therefore a decision procedure. Rewriting with $\overrightarrow{\mathcal{E}}_{c c_{B}^{\succ}(\bar{\Gamma})}$ is called contextual rewriting [73], since we are using the "context" $\bar{\Gamma}$ suitably transformed into $c c_{B}^{>}(\bar{\Gamma})$. Many increasingly more powerful variations on this method are possible. For example, we may replace $(\Sigma, B)$ by $\mathcal{E}=(\Sigma, E \cup B)$, with $\overrightarrow{\mathcal{E}}$ ground convergent and then rewrite $\bar{u}=\bar{v}$ not only with $c c_{B}^{>}(\bar{\Gamma})$ but also with $\overrightarrow{\mathcal{E}}$. Likewise, when performing inductive reasoning we may consider not just a ground equation $\bar{u}=\bar{v}$, but a ground QF formula $\bar{\varphi}$ (whose premise is $\bar{\Gamma}$ ), and rewrite $\bar{\varphi}$ not only with $c c_{B}^{>}(\bar{\Gamma})$ but also with $\overrightarrow{\mathcal{E}_{U}}=$

### 2.8 Variant Unification and Variant Satisfiability in a Nutshell

Consider an order-sorted equational theory $\mathcal{E}=(\Sigma, E \cup B)$ such that $\overrightarrow{\mathcal{E}}$ is ground convergent and suppose we have a constructor subspecification $\left(\Omega, B_{\Omega}, \varnothing\right) \subseteq(\Sigma, B, \vec{E})$, so that $\left.T_{\mathcal{E}}\right|_{\Omega} \cong T_{\Omega / B_{\Omega}}$. Suppose, further, that we have a subtheory $\mathcal{E}_{1} \subseteq \mathcal{E}$ such that: (i) $\overrightarrow{\mathcal{E}}_{1}$ is convergent and has the finite variant property ${ }^{6}$ (FVP) [24], (ii) $\overrightarrow{\mathcal{E}_{1}}$ can be "sandwiched" between $\overrightarrow{\mathcal{E}}$ and the constructors as $\left(\Omega, B_{\Omega}, \varnothing\right) \subseteq\left(\Sigma_{1}, B_{1}, \vec{E}_{1}\right) \subseteq(\Sigma, B, \vec{E})$, (iii) $B_{1}$ can involve any combination of associativity and/or commutativity and/or identity axioms, ${ }^{7}$ and (iv) $\left.T_{\mathcal{E}}\right|_{\Sigma_{1}} \cong T_{\mathcal{E}_{1}}$, which forces $\left.T_{\mathcal{E}_{1}}\right|_{\Omega} \cong T_{\Omega / B_{\Omega}}$.

Then, if $\Gamma$ is a conjunction of $\Sigma_{1}$-equations, since $\left.T_{\mathcal{E}}\right|_{\Omega} \cong T_{\Omega / B_{\Omega}}$, a ground $\mathcal{E}$-unifier $\rho$ of $\Gamma$ is always $\mathcal{E}$-equivalent to its normal form $\rho!\overrightarrow{\mathcal{E}}$, which, by definition, is the substitution $\lambda x \in \operatorname{dom}(\rho) . \rho(x)!_{\overrightarrow{\mathcal{E}}}$. Therefore, by ground convergence and sufficient completeness, $\rho!_{\vec{\varepsilon}}$ is a ground $\Omega$-substitution, that is, a constructor ground $\mathcal{E}$-unifier of $\Gamma$. But since $\Omega \subseteq \Sigma_{1}$ and $\left.T_{\mathcal{E}}\right|_{\Sigma_{1}} \cong T_{\mathcal{E}_{1}}$, which implies $\left.C_{\Sigma / E, B}\right|_{\Sigma_{1}} \cong C_{\Sigma_{1} / E_{1}, B_{1}}$, this makes $\rho!_{\overrightarrow{\mathcal{E}}}$ a constructor ground $\mathcal{E}_{1}$-unifier of $\Gamma$. But, under the assumptions for $B_{1}$, by the results in [54|70]56] one can compute a complete, finite $8^{8}$ set $U n i f_{\mathcal{E}_{1}}^{\Omega}(\Gamma)$ of constructor $\mathcal{E}_{1}$-unifiers of $\Gamma$, so that any constructor ground $\mathcal{E}_{1}$-unifier of $\Gamma$, and therefore up to $\mathcal{E}$-equivalence any ground $\mathcal{E}$-unifier of $\Gamma$, is an instance of a unifier in $U n i f_{\mathcal{E}_{1}}^{\Omega}(\Gamma)$.

Note, furthermore, that if $B_{1}$ does not contain associativity without commutativity axioms, $\left(\Omega, B_{\Omega}\right)$ is an OS-compact theory [54] (resp. a weakly OS-compact theory if $B_{1}$ does contain associativity without commutativity axioms and ( $\Omega, B_{\Omega}$ ) satisfies some additional assumptions [56]). Therefore, again by [54] (resp. [56]) satisfiability (and therefore validity) of any $\mathrm{QF} \Sigma_{1}$-formula in $T_{\mathcal{E}_{1}}$, and by $\left.T_{\mathcal{E}}\right|_{\Sigma_{1}} \cong T_{\mathcal{E}_{1}}$ also in $T_{\mathcal{E}}$, is decidable (resp. has a partial decidability algorithm under some assumptions as explained in [56]). In the

[^5]inductive inference system presented in Section 4 this decidability is exploited by the VARSAT simplification rule.

### 2.9 Generator Sets and Function Subcalls

Generator sets generalize standard structural induction on the constructors of a sort, in the sense that structural induction inducts on a specific generator set. They are particularly useful for inductive reasoning when constructors obey structural axioms $B$ including associativity or associativity-commutativity for which structural induction may prove ill-suited; but, even for free constructors, structural induction may still be ill-suited for inducting on a variable under a function equationally defined in a manner other than by standard primitive recursion.

A generator set for a sort $s$ is just a set of constructor terms patterns -of sort $s$ or smaller- such that, up to $B$-equality, any ground constructor term of sort $s$ is a ground substitution instance of one of the patterns in the generator set. For example, structural induction on the Peano natural numbers is achieved by the generator set $\{0, s(n)\}$ for sort Nat, but the alternative generator set $\{0, s(0), s(s(n))\}$ may be better suited to reason about functions defined by the two "base cases" 0 and $s(0)$, and inducting on $s(s(n))$, such as, for example, addition defined by the equations: $x+0=x, x+s(0)=s(x), x+s(s(y))=$ $s(s(x+y))$, which can add numbers roughly twice as fast as the standard definition of addition.

The usefulness of generator sets is even greater for constructors that satisfy structural axioms such as $A$ or $A C$. Let us see an example.

Example 1. Let us consider a generator set for $\cup_{\_}$a (subsort-overloaded) associativecommutative ( $A C$ ) multiset union operator on multisets of elements, involving subsort inclusions Elt $<$ NeMSet $<$ MSet, with constructors $\Omega$ including $\varnothing$ of sort MSet and the
 multisets, whereas the overloading _ $\cup_{\_}:$MSet MSet $\rightarrow$ MSet of $\cup_{\_}$for the sort MSet is a defined symbol, namely, defined by the equation: $S \cup \varnothing=S$, with $S$ of sort MSet. Then, the set $\{\varnothing, x, U \cup V\}$, with $x$ of sort Elt and $U, V$ of sort NeMSet, can be seen as the generator set for sort MSet corresponding to structural induction. But the generator set $\{\varnothing, x, y \cup U\}$, with $y$ also of sort $E l t$, is much better suited to reason about a multiset membership predicate _ $\in$ defined by equations including, among others, $x \in \varnothing=$ false, $x \in x=$ true, $x \in x \cup U=$ true .

If the set $B$ of structural axioms among constructors $\Omega$ decomposes as a disjoint union $B=B_{0} \uplus U$, with $B_{0}$ associative and/or commutative axioms, and $U$ unit (identity) axioms, it is better to consider generator sets modulo $B_{0}$, instead of modulo $B$. The reason for this choice is that the axioms $B_{0}$ are term-size-preserving, but the axioms $U$ are not so, and this can cause technical complications when reasoning inductively about proper constructor subterms of a term. For example, if we had added an axiom $U_{\varnothing}$ for $\varnothing$ as a unit element for $\cup^{\circ}$ _ instead of specifying $S \cup \varnothing=S$ as a defining equation, then $\{\varnothing, x \cup U\}$ would indeed be a generator set modulo $A C U$ for sort MSet, but a term like $a \cup \varnothing$ collapses modulo $B$ to its proper subterm $a$, and is, for that reason, problematic for inductive reasoning on subterms. Here is the precise definition that will be used for inductive reasoning purposes:

Definition 1. For $\Omega$ an order-sorted signature of constructors satisfying axioms $B$ decomposable as $B=B_{0} \uplus U$, as explained above, and s a sort in $\Omega$, a $B_{0}$-generator set for sort s is a finite set of terms $\left\{u_{1}, \ldots, u_{k}\right\}$, with $u_{1}, \ldots, u_{k} \in T_{\Omega}(X)_{s}$ and such that $T_{\Omega / B_{0}, s}=\left\{\left[u_{i} \rho\right] \in T_{\Omega / B_{0}, s} \mid 1 \leqslant i \leqslant k, \rho \in\left[X \rightarrow T_{\Omega}\right]\right\}$.

In practice one may use several generator sets for the same sort $s$, depending on the various functions that one may wish to reason inductively about. Furthermore, one may be able to generate such sets automatically from the function definitions themselves 9 assuming that defined functions have been proved sufficiently complete with respect to $\Omega$.

Checking the Correctness of Generator Sets. How can we know that a proposed generator set $\left\{u_{1}, \ldots, u_{k}\right\}$ it truly one modulo axioms $B_{0}$ for a given sort $s$ and constructors $\Omega$ ? Assuming that the terms $u_{1}, \ldots, u_{k}$ are all linear, i.e., have no repeated variables -which is the usual case for generator sets- this check can be reduced to an automatic sufficient completeness check with Maude's Sufficient Completeness Checker (SCC) tool [37], which is based on tree automata decision procedures modulo axioms $B_{0}$. The reduction is extremely simple: define a new unary predicate $s: s \rightarrow$ Bool with equations $s\left(u_{i}\right)=t r u e$, $1 \leqslant i \leqslant k$. Then, $\left\{u_{1}, \ldots, u_{k}\right\}$ is a correct generator set for sort $s$ modulo $B_{0}$ for the constructor signature $\Omega$ iff the predicate $s$ is sufficiently complete, which can be automatically checked by the SCC tool. Furthermore, if $\left\{u_{1}, \ldots, u_{k}\right\}$ is not a generator set for sort $s$, the SCC tool will output a useful counterexample.

Function Subcalls. Function definitions usually involve recursive (and possibly conditional) equations oriented as rules of the form:

$$
[l]: f(\vec{u}) \rightarrow t\left[f\left(\overrightarrow{u_{1}}\right), \ldots, f\left(\overrightarrow{u_{k}}\right)\right]_{p_{1}, \ldots, p_{k}} \text { if } \operatorname{cond}\left[f\left(\overrightarrow{v_{1}}\right), \ldots, f\left(\overrightarrow{v_{k^{\prime}}}\right)\right]_{q_{1}, \ldots, q_{k^{\prime}}}
$$

where all the terms in $\vec{u}, \overrightarrow{u_{1}}, \ldots, \overrightarrow{u_{k}}$ and $\overrightarrow{v_{1}}, \ldots, \overrightarrow{v_{k^{\prime}}}$ are constructor terms, and at positions $p_{1}, \ldots, p_{k}$ in the righthand side $t$, and $q_{1}, \ldots, q_{k^{\prime}}$ in the condition cond, with $k+k^{\prime} \geqslant 1$, new calls $f\left(\overrightarrow{u_{1}}\right), \ldots, f\left(\overrightarrow{u_{k}}\right)$ and $f\left(\overrightarrow{v_{1}}\right), \ldots, f\left(\overrightarrow{v_{k^{\prime}}}\right)$ to $f$, which we shall call the subcalls with constructor arguments $\sqrt{10}$ of the rule, appear. In reasoning inductively about $f$ after applying such a rule, it can be highly advantageous to have inductive hypotheses available for such subcalls.

For the same technical reasons already mentioned, of avoiding $U$-collapses of a constructor term to a proper subterm, we shall consider such rules $[l]$, not in the original ground convergent rewrite theory $\overrightarrow{\mathcal{E}}$ of interest, but in the semantically-equivalent transformed theory ${ }^{111} \overrightarrow{\mathcal{E}}_{U}$. Under such assumptions, $S C([l])$ will denote the set

$$
S C([l])=\left\{f\left(\overrightarrow{u_{1}}\right), \ldots, f\left(\overrightarrow{u_{k}}\right), f\left(\overrightarrow{v_{1}}\right), \ldots, f\left(\overrightarrow{v_{k^{\prime}}}\right)\right\}
$$

of subcalls with constructor arguments of rule $[l]$.
Intuitively, we should be able to induct on a subcall $f(\vec{v})$ of a main call $f(\vec{u})$ if $f(\vec{v})$ is smaller than $f(\vec{u})$ just in the same way than, if $s(x)$ belongs to a generator set for the sort Nat, we can induct on the smaller term $x$. This leads us to the notion of a (proper) subterm subcall of a main call $f(\vec{u})$. For example, $f(s(x), s(y))$ may be the main call in the

[^6]lefthand side of one of the rules defining $f$, which may have two subcalls in its righthand side and/or its condition, say, $f(x, s(y))$, and $f(x, x)$. Then, $f(x, s(y))$ is a (proper) subterm subcall of $f(s(x), s(y))$ —because $x$ is a proper subterm of $s(x)$, and $s(y)$ is a (non-proper) subterm of $s(y)$ - but $f(x, x)$ is not a subterm subcall of $f(s(x), s(y))$-because $x$ is not a subterm of $s(y)$.

In the presence of structural axioms $B_{0}$ of associativity and/or commutativity among constructors, the notions of: (1) (proper) subterm (modulo $B_{0}$ ); and (2) (proper) subterm subcall (modulo $B_{0}$ ) are somewhat more subtle. We first need to recall the wellfounded immediate subterm relation $\triangleleft$, where, for any $\Sigma$-term $f\left(t_{1}, \ldots, t_{n}\right)$, the relation $t_{i} \triangleleft f\left(t_{1}, \ldots, t_{n}\right)$ holds, by definition, for $1 \leqslant i \leqslant n$, as well as its transitive, $\triangleleft^{+}$, and reflexivetransitive, $\triangleleft^{*}$, closures.

Definition 2. Assuming that $B_{0}$ are axioms of associativity and/or commutativity, a term $u$ is called a $B_{0}$-proper subterm of $v$, denoted $u \triangleleft_{B_{0}}^{+} v$, iff there exists a term $v^{\prime}$ such that $v=B_{B_{0}} v^{\prime}$ and $u \triangleleft^{+} v^{\prime}$. The set $P S T_{B_{0}}(v)$ of all proper $B_{0}$-subterms of the $\Sigma$-term $v$ is then, $P S T_{B_{0}}(v)=\left\{u \mid u \triangleleft_{B_{0}}^{+} v\right\}$.

Remark 1. Note that the set $P S T_{B_{0}}(t)$ can be quite large. In practice, what we are interested in is the much smaller set $\left\{[v] \mid v \in P S T_{B_{0}}(t)\right\}$, where $[v]$ denotes the $B_{0}$-equivalence class of [ $v]$. That is, we identify any two proper $B_{0}$-subterms of $t$ up to $B_{0}$-equality. Without further ado, $P S T_{B_{0}}(t)$ will be understood in this sense, that is, as a choice in the equivalence class $[v]$ of any $v \in P S T_{B_{0}}(t)$, with all other equivalent choices discarded as redundant.

We can now characterize notion (2), namely, that of a proper subterm subcall, as follows:

Definition 3. Let $\overrightarrow{\mathcal{E}}$ be a ground convergent rewrite theory with $\overrightarrow{\mathcal{E}}_{U}$ its semantically equivalent transformed theory where identity axioms in $\mathcal{E}$ have been transformed into rules in $\overrightarrow{\mathcal{E}}_{U}$, so that $\overrightarrow{\mathcal{E}}_{U}$ only satisfies associativity and/or commutativity axioms $B_{0}$. Let $[l]$ be a possibly conditional rule in $\overrightarrow{\mathcal{E}}_{U}$ with constructor argument calls whose lefthand side is $f(\vec{u})$. Then, the set $\operatorname{SSC}([l])$ of its (proper) subterm subcalls is, by definition, the set:

$$
S S C([l])=\left\{f(\vec{w}) \in S C([l]) \mid \exists f\left(\overrightarrow{u^{\prime}}\right) \text { s.t. } f(\vec{u})={ }_{B_{0}} f\left(\overrightarrow{u^{\prime}}\right) \wedge \vec{w} \triangleleft^{+} \overrightarrow{u^{\prime}}\right\}
$$

where, by definition, if $\vec{w}=w_{1}, \ldots, w_{n}$ and $\overrightarrow{u^{\prime}}=u_{1}^{\prime}, \ldots, u_{n}^{\prime}$, then $\vec{w} \triangleleft^{+} \overrightarrow{u^{\prime}}$ iff $(i) w_{i} \triangleleft^{*} u_{i}^{\prime}$, $1 \leqslant i \leqslant n$, and (ii) exists $j, 1 \leqslant j \leqslant n$, such that $w_{j} \triangleleft^{+} u_{j}^{\prime}$.

Consider, for example, a Boolean predicate ordered on lists of natural numbers with an associative ( $A$ ) constructor symbol _• involving, among others, the rule:
$[l]:$ ordered $(n \cdot m \cdot L) \rightarrow$ if $n \leqslant m$ then ordered $(m \cdot L)$ else false $f i$.
Then, $\operatorname{SSC}([l])=S C([l])=\{\operatorname{ordered}(m \cdot L)\}$.

### 2.10 Ordered Rewriting

In inductive theorem proving one should try to use induction hypotheses as much as possible to simplify conjectures. But this raises two obvious questions: (1) In what sense should a conjecture be made simpler? (2) How can an induction hypothesis be used for this purpose? There are various answers given to questions (1) and (2). Ordered rewriting answers them as follows: Question (1) is answered by suggesting that a conjecture $\varphi$
should become simpler by being transformed into a smaller conjecture $\varphi^{\prime}$, in the sense that $\varphi>\varphi^{\prime}$, for $>$ a suitable reduction order (for reduction orders see, e.g., [2]). Question (2) is answered by proposing the ordered rewriting relation ${ }^{12} \varphi \rightarrow>\varphi^{\prime}$ for this purpose.

Assuming our induction hypotheses are clauses, $\Gamma \rightarrow \Delta$, with $\Gamma$ a conjunction and $\Delta$ a disjunction of equations, it is worth considering a (by no means exhaustive) natural taxonomy of clauses associated to a reduction order $>$ on terms:

1. Reductive equation, $w_{0}=w_{1}$ such that, for some $i \in\{0,1\}, \operatorname{vars}\left(w_{i}\right) \supseteq \operatorname{vars}\left(w_{i+2}\right)$ and $w_{i}>w_{i+{ }_{2} 1}$, in which case, the equation can be oriented as a rewrite rule $w_{i} \rightarrow w_{i+{ }_{2} 1}$, where +2 denotes addition modulo 2 . We then call $w_{i}$ the equation's lefthand side .
2. Reductive conditional equation, $u_{1}=v_{1}, \ldots, u_{n}=v_{n} \rightarrow w_{0}=w_{1}$ such that: (i) $w_{0}=w_{1}$ is reductive with lefthand side $w_{i}$, (ii) $\operatorname{vars}\left(w_{i}\right) \supseteq \operatorname{vars}\left(u_{1}\right) \cup \operatorname{vars}\left(v_{1}\right) \cup \ldots \cup \operatorname{vars}\left(u_{n}\right) \cup$ $\operatorname{vars}\left(v_{n}\right)$, and (iii) $w_{i}>u_{1}, v_{1}, \ldots, u_{n}, v_{n}$. A reductive conditional equation can be oriented as a conditional rewrite rule $w_{i} \rightarrow w_{i+21}$ if $u_{1}=v_{1} \wedge \ldots, \wedge u_{n}=v_{n}$.
3. Usable equation, $w_{0}=w_{1}$, a non-reductive equation such that for some $i \in\{0,1\}$, $\operatorname{vars}\left(w_{i}\right) \supseteq \operatorname{vars}\left(w_{i+{ }_{2} 1}\right)$. The set of $w_{i}$ satisfying this property is called the set of candidate lefthand sides, denoted $\operatorname{cand}\left(w_{0}=w_{1}\right)$.
4. Usable conditional equation, a non-reductive $u_{1}=v_{1}, \ldots, u_{n}=v_{n} \rightarrow w_{0}=w_{1}$ such that either: (i) $w_{0}=w_{1}$ is reductive with lefthand side $w_{i}$, and $\operatorname{vars}\left(w_{i}\right) \supseteq$ $\operatorname{vars}\left(u_{1}\right) \cup \operatorname{vars}\left(v_{1}\right) \cup \ldots \cup \operatorname{vars}\left(u_{n}\right) \cup \operatorname{vars}\left(v_{n}\right)$; or (ii) $w_{0}=w_{1}$ is usable, and if $w_{i} \in \operatorname{cand}\left(w_{0}=w_{1}\right)$, then $\operatorname{vars}\left(w_{i}\right) \supseteq \operatorname{vars}\left(u_{1}\right) \cup \operatorname{vars}\left(v_{1}\right) \cup \ldots \cup \operatorname{vars}\left(u_{n}\right) \cup \operatorname{vars}\left(v_{n}\right)$. The set of candidate lefthand sides for such a conditional equation is $\left\{w_{i}\right\}$ in case (i), and $\operatorname{cand}\left(w_{0}=w_{1}\right)$ in case (ii).
5. Unusable equation, conditional or not. But this does not mean that they could not be used in other ways, even for rewriting in a user-guided maner.
6. Clauses $\Gamma \rightarrow \Delta$ with more than one disjunct in $\Delta$. Not being equations, they cannot be oriented as $\Sigma$-rewrite rules; but we shall see in Section 3.2 that, under mild conditions, they can be oriented as $\Sigma^{=}$-rewrite rules (recall Section 2.5).

What is attractive about this taxonomy is its simplicity and the easy, syntactic way one can, given a reduction order $>$ on terms, determine where a given clause falls in the above pecking order. Since induction hypotheses are generated dynamically as part of the inductive deduction process, the above taxonomy provides an inexpensive way to determine if and how any such hypothesis can be used for simplification. Specifically, equations falling in categories (1) and (2) are immediately usable by standard rewriting (modulo axioms $B$ if they are present in the given specification and $>$ is $B$-compatible, i.e., if it defines an order, not just on terms $u>v$, but on $B$-equivalence classes $[u]>[v]$ ). Furthermore, rewriting modulo axioms $B$ with reductive equations oriented as rules is guaranteed to terminate thanks to $>$. Specifically, unconditional (resp. conditional) rewriting with reductive rules is terminating (resp. operationally terminating in the sense of [44]). Termination is extremely useful for any simplification process. The next two categories, (3) and (4), are the whole point and focus of ordered rewriting: how to use them for simplification with the order $>$, an idea coming from both term rewriting and paramodulationbased theorem proving (see, e.g., [47/4[59]). Let us begin with category (3):

Definition 4. (Unconditional Ordered Rewriting Modulo). For $\Sigma$ a kind-complete and $B$-preregular ordered-sorted signature, and B a set of equational $\Sigma$-axioms, given a set

[^7]$G$ of usable $\Sigma$-equations and a reduction order $>$ on $\Sigma$-terms compatible with $B$, the ordered rewriting relation modulo $B$, denoted $t \rightarrow_{G, B>} t^{\prime}$, or sometimes $t \rightarrow{ }_{G, B\rangle}^{\theta} t^{\prime}$, holds between $\Sigma$-terms $t$ and $t^{\prime}$ iff there exist: (i) an equation $\left(w_{0}=w_{1}\right) \in G$, (ii) a position $p$ in $t$, (iii) a candidate lefthand side $w_{i} \in \operatorname{cand}(e)$, and (iv) a substitution $\theta$, such that: (a) $\left.t\right|_{p}={ }_{B} w_{i} \theta$, (b) $w_{i} \theta>w_{i+21} \theta$, and (c) $t^{\prime} \equiv t\left[w_{i+{ }_{2} 1} \theta\right]_{p}$.

The relation $t \rightarrow{ }_{G, B>}^{\otimes} t^{\prime}$ holds between t and $t^{\prime}$ iff either $(i) t={ }_{B} t^{\prime}$, or $\left(\right.$ ii) $t \rightarrow_{G, B>}^{+} t^{\prime}$. Note that, since $>$ is a reduction order modulo $B, \rightarrow_{G, B>}$ is always a terminating relation.

Intuitively, if, say, $\left\{w_{0}, w_{1}\right\}=\operatorname{cand}\left(w_{0}=w_{1}\right)$, we can think of ordered rewriting with $w_{0}=w_{1}$ as equivalent to rewriting with two conditional rules: (i) $w_{0} \rightarrow w_{1}$ if $w_{0}>w_{1}$, and (ii) $w_{1} \rightarrow w_{0}$ if $w_{1}>w_{0}$, or just one such rule if $\operatorname{cand}\left(w_{0}=w_{1}\right)$ is a singleton set. It is a form of "constrained rewriting," where the constraint is specified by means of the reduction order $>$.

For category (4) the notion of conditional ordered rewriting is somewhat more involved. However, the effectiveness in both categories (3) and (4) can be significantly increased by making ordered rewriting (conditional or not) background theory aware. As it turns out, background theory awareness will make the definition of conditional ordered rewriting simpler, since no extra requirements on termination of condition evaluation will be needed.

Making Order Rewriting Background-Theory-Aware. Sometimes, ordered rewriting should deliver the goods, but it doesn't. Let us consider a simple example.

Example 2. Consider the theory $\mathcal{N}$ giving the usual definition of natural number addition in Peano notation: $n+0=n, n+s(m)=s(n+m)$, and suppose we want to prove the commutativity law $x+y=y+x$ by standard induction, inducting on $x$. Let us focus on the proof for the induction step, i.e., on proving the subgoal $s(\bar{x})+y=y+s(\bar{x})$ with induction hypothesis $\bar{x}+y=y+\bar{x}$ (where $\bar{x}$ is a fresh constant), which simplifies to $s(\bar{x})+y=s(y+\bar{x})$ because ordered rewriting with the induction hypothesis is ineffective at this point. We induct again, now on $y$. Let us focus on the base case, where we get the sub-subgoal $s(\bar{x})+0=s(0+\bar{x})$, which simplifies to $s(\bar{x})=s(0+\bar{x})$, and, using the theory $\mathcal{N}^{=}$that adds an equationally-defined equality predicate to $\mathcal{N}$ (see Section 2.5), it further simplifies ${ }^{13}$ to $\bar{x}=0+\bar{x}$. We would now like to use ordered rewriting with the induction hypothesis $\bar{x}+y=y+\bar{x}$ to further simplify this sub-subgoal with matching substitution $\{y \mapsto 0\}$. But, since when extending the total RPO order based on the total order on symbols $+>s>0$, its natural extension is based on $+\succ s>\bar{x}>0$, we cannot apply order rewriting here, since $0+\bar{x} \nsucc \bar{x}+0$ in the standard RPO order.

This is frustrating, because the 0 in the righthand side's instance is a silly obstacle blocking the rule's application, which could, for example, be removed by first instantiating the induction hypothesis to this case as $\bar{x}+0=0+\bar{x}$ and then simplifying it to $\bar{x}=0+\bar{x}$, so that with this simplified instance of the hypothesis ordered rewriting would actually succeed in proving this sub-subgoal.

This raises the following question: is there a way of making ordered rewriting backgroud theory aware, so as to substantially increase its chances of success in situations such as the one above? In this case, the "background theory" is of course $\mathcal{N}$ or, more

[^8]generally, $\boldsymbol{N}^{=}$. In general, it may also include other induction hypotheses and possibly some already-proved lemmas.

The answer to this question is an emphatic Yes! Recall that, conceptually, ordered rewriting with $\bar{x}+y=y+\bar{x}$ is rewriting with the conditional constrained rules:

$$
\bar{x}+y \rightarrow y+\bar{x} \text { if } \bar{x}+y>y+\bar{x} \quad \text { and } \quad y+\bar{x} \rightarrow \bar{x}+y \text { if } y+\bar{x}>\bar{x}+y .
$$

Of course, as given, these rules cannot exploit at all the presence of a background theory. But they can do so in a more subtle version of ordered rewriting, as the rules:
$\bar{x}+y \rightarrow z$ if $z:=y+\bar{x} \wedge \bar{x}+y>z \quad$ and $\quad y+\bar{x} \rightarrow z$ if $z:=\bar{x}+y \wedge y+\bar{x}>z$
where we are using Maude's "matching condition" notation, so that, for example, evaluating, say, the first rule's condition $z:=y+\bar{x}$ for a lefthand side's matching substitution $\theta$ means: (i) normalizing $(y+\bar{x}) \theta$ to, say, $u$, and (ii) then performing the comparison $(\bar{x}+y) \theta>u$. In the notation of conditional term rewriting systems (see, e.g., [61]) this would be described as a "deterministic 3-CTRS" conditional rewrite rule of the form: $\bar{x}+y \rightarrow z$ if $y+\bar{x} \rightarrow z \wedge \bar{x}+y>z$. However, this description is still a bit too simplistic, since it fails to distinguish between equational and non-equational rewrite rules (see Section 2.3 and Footnote 14 below).

This new method of contextual rewriting is indeed "background theory aware," for the simple reason that the normalization of expressions in a matching condition uses the equational ${ }^{14}$ rewrite rules available, which include those in the background equational theory. In fact, the above recalcitrant sub-subgoal $\bar{x}=0+\bar{x}$ can be immediately discharged with the rule $y+\bar{x} \rightarrow z$ if $z:=\bar{x}+y \wedge y+\bar{x}>z$, since $\bar{x}+0$ normalizes to $\bar{x}$, and $0+\bar{x}>\bar{x}$.

The moral to be drawn from this example is that there is a general theory transformation from usable equations (conditional or not, i.e., from equations in categories (3)-(4)) to conditional rewrite rules that supports background theory awareness: given a usable conditional equation of the form: $u=v$ if cond (in category (3), cond $=\mathrm{T}$ ), assuming, say, that both $u$ and $v$ are candidate lefthand sides, we transform it into the constrained conditional rewrite rules:

$$
u \rightarrow z \text { if } z:=v \wedge u>z \wedge \text { cond } \quad \text { and } \quad v \rightarrow z \text { if } z:=u \wedge v>z \wedge \text { cond }
$$

with $z$ a fresh variable whose sort is the top sort in the connected component of sorts including those of $u$ and $v$. Of course, if there is only one candidate lefthand side, only one such rule is generated. And if $u>v$ (resp. $v>u$ ), we only need to generate the simpler rule: $u \rightarrow v$ if cond (resp. $v \rightarrow u$ if cond). To the best of my knowledge this form of ordered rewriting appears to be new. Background theory awareness can make ordered rewriting considerably more likely to succeed. Success can be even more dramatic in the case of conditional usable equations (category (4)), since, assuming the background equational

[^9]theory is terminating, the evaluations of conditions always terminates. That is, all usable equations in categories (3)-(4) become in this way executable in a terminating way.

But we can do even better: (i) we can associate to a conditional equation $u_{1}=v_{1}, \ldots, u_{n}=$ $v_{n} \rightarrow w_{0}=w_{1}$ that is reductive with lefthand side $w_{i}$ (category (2)) the rule:

$$
w_{i} \rightarrow w_{i+21} \text { if } \bigwedge_{1 \leqslant i \leqslant n}\left(u_{i} \equiv v_{i}\right) \rightarrow t t
$$

where we have added a fresh new sort Pred with constant $t t$ to the signature $\Sigma$ as well as a new operator $\equiv_{-}$of sort Pred, and new rules $x \equiv x \rightarrow t t$ for each $x$ whose sort is the top of a connected component of $\Sigma$; (ii) likewise, for a usable conditional equation $w_{1}=w_{2}$ if $\bigwedge_{1 \leqslant i \leqslant n} u_{i}=v_{i}$ in category (4) with $w_{i} \in \operatorname{cand}\left(w_{0}=w_{1}\right)$ such that $w_{i}>$ $u_{1}, v_{1}, \ldots, u_{n}, v_{n}$, we can modify the above transformation from a usable conditional equation into a conditional rewrite rule by associating to the choice of lefthand side $w_{i}$ the rule:

$$
w_{i} \rightarrow z \text { if } z:=v \wedge u>z \wedge \bigwedge_{1 \leqslant i \leqslant n}\left(u_{i} \equiv v_{i}\right) \rightarrow t t
$$

The main difference in case (ii) is that, if the above requirement $w_{i}>u_{1}, v_{1}, \ldots, u_{n}, v_{n}$ does not hold, in a rule application the instance of the condition $\bigwedge_{1 \leqslant i \leqslant n} u_{i}=v_{i}$ is only evaluated with equations. Instead, now, the rewrite condition $\bigwedge_{1 \leqslant i \leqslant n}\left(u_{i} \equiv v_{i}\right) \rightarrow t t$ is evaluated with both equations and rules. The same applies to case (i): the condition is now evaluated with equations and rules. Since in our inductive theorem proving applications both reductive conditional equations and usable equations will be induction hypotheses used for goal simplification, what this means in practice is that, when applying a conditional equational hypothesis to simplify a goal, in cases (i)-(ii) above we can use (executable) induction hypotheses themselves, and not just the ground convergent equations in the original theory, to evaluate the hypothesis' condition, which gives us a better chance of success. This both ensures termination of goal simplification with equational hypotheses, and, in cases (i)-(ii) above, increases the chances that such hypotheses will be applied, since, the evaluation of their conditions will be more likely to succeed.

The main import of this entire discussion for the rest of this paper is that, without further ado, in any future mention and use of the words "ordered rewriting" we will always mean ordered rewriting in the background theory aware version defined above.

### 2.11 Existential Formula Quantification with Skolem Signatures

What is the model-theoretic meaning of a universally (resp. existentially) quantified sentence $\left(\forall x_{1}, \ldots, x_{n}\right) \varphi$ (resp. $\left(\exists x_{1}, \ldots, x_{n}\right) \varphi$ ) being satisfied on a $\Sigma$-algebra $A$ ? It exactly means that the sentence $\bar{\varphi}$, where $\bar{\varphi} \equiv \varphi\left\{x_{1} \mapsto \bar{x}_{1}, \ldots, x_{n} \mapsto \bar{x}_{n}\right\}$, is satisfied in all (resp. some) $\Sigma\left(\left\{\bar{x}_{1}, \ldots, \bar{x}_{n}\right\}\right)$-algebras $B$ that have $A$ as their $\Sigma$-reduct, i.e., such that $\left.B\right|_{\Sigma}=A$. The constants $\bar{x}_{1}, \ldots, \bar{x}_{n}$ are called the Skolem constants involved in this business, in honor of Thoralf Skolem. But why quantifying (universally or existentially) only on (Skolemized) variables? After all, we know, thanks to Skolem, that we can also quantify on function symbols; and that this is the essential trick ("Skolemization") allowing us to reduce the satisfaction of all first-order formulas (first put in prenex normal form) to that of quantifier-free formulas (for detailed treatments of prenex normal form and Skolemization see, e.g., [35]3]). All this is eminently relevant for our purposes in this paper, since inductive theorem proving is just proving the satisfaction of a formula $\varphi$ in the initial algebra $T_{\mathcal{E}}$ of an equational theory $\mathcal{E}$ with, say, signature $\Sigma$. But which formulas? There are very good practical reasons to stick to quantifier-free ones; but we can introduce quantified formulas through the back door of Skolemization.

A simple example may help at this point. Suppose that we have specified the Peano natural numbers in an unsorted equational theory $\mathcal{N}$ with constructors 0 and $s$, the obvious equations for,$+ *$, and natural division div, and a Boolean predicate even, defined by the equations: even $(0)=\operatorname{true}, \operatorname{even}(s(0))=$ false, and even $(s(s(n)))=\operatorname{even}(n)$. A simple property we might like to prove is the following:

$$
\operatorname{even}(n)=\operatorname{true} \Rightarrow(\exists m) n=s(s(0)) * m
$$

which Skolemized becomes:

$$
(\exists f) \text { even }(n)=\text { true } \Rightarrow n=s(s(0)) * f(n) .
$$

In general, of course, there may be, not just one, but several Skolem constants and functions in a formula like this. But what does this mean? In an order-sorted setting, it just means that we are quantifying (existentially in this case) over an order-sorted signature -let us call it a Skolem signature, and denote it by $\chi$ - with the exact same poset of sorts $(S, \leqslant)$ as our original signature $\Sigma$, so that a quantifier-free Skolemized formula is just a quantifier-free $\Sigma \cup \chi$-formula $\psi$, and the satisfaction of its universal (resp. existential) quantification, $(\forall \chi) \psi$ (resp. $(\exists \chi) \psi)$ in a $\Sigma$-algebra $A$ has the expected meaning: $A \models(\forall \chi) \psi($ resp. $A \models(\exists \chi) \psi)$ iff it is the case that in all (resp. in some) of the $\Sigma \cup \chi$ algebras $B$ such that $\left.B\right|_{\Sigma}=A, B \models \psi$ holds.

But then, what does it mean to prove, that a $\Sigma$-algebra $A$ satisfies an existentially quantified Skolemized formula? For example, that the initial algebra $T_{\mathcal{N}}$ of our example satisfies $(\exists f)$ even $(n)=$ true $\Rightarrow n=s(s(0)) * f(n)$ ? It exactly means to show that there is an interpretation of $f$ as a unary function in $T_{\mathcal{N}}$, let us denote it $f_{T_{\mathcal{N}}}: T_{\mathcal{N}} \rightarrow T_{\mathcal{N}}$, satisfying the formula even $(n)=$ true $\Rightarrow n=s(s(0)) * f(n)$ in $T_{\mathcal{N}}$. But how can we specify such a function $f_{T_{N}}$ ? Well, the best possible situation is when we are lucky enough that $f_{T_{N}}$ is definable as a $\Sigma$-functional expression, i.e., when we can define $f_{T_{N}}$ by means of a definitional extension of our theory $\mathcal{N}$ of the form: $f(n)=t(n)$, for $t(n)$ a $\Sigma$-term. In this example we are lucky, since we can define $f(n)=\operatorname{div}(n, s(s(0))$, so that we just have to prove the inductive theorem:

$$
\operatorname{even}(n)=\operatorname{true} \Rightarrow n=s(s(0)) * \operatorname{div}(n, s(s(0)) .
$$

In general, of course, this may not be the case (for example, if we had not yet specified the div function in $\mathcal{N}$ ). However, thanks to the Bergstra-Tucker Theorem [9], any total computable function can be specified in a finitary theory extension protecting the given data type by a finite number of confluent and terminating equations. What is the upshot of all this in practice? The following: To prove that an initial algebra $T_{\mathcal{E}}$ with signature $\Sigma$ satisfies an existentially quantified Skolemized formula of the form $(\exists \chi) \psi$, with $\psi$ quantifier-free we can:

1. First, find, if possible, a theory interpretation (called a view in Maude [13]) $I: \chi \rightarrow \mathcal{E}$ that is the identity on sorts, and maps each $f: s_{1}, \ldots s_{n} \rightarrow s$ (including consants) in $\chi$ to a $\Sigma$-term $t_{f}\left(x_{1}: s_{1}, \ldots, x_{n}: s_{n}\right)$ of sort $s$ in $\mathcal{E}$. This is equivalent to adding to $\mathcal{E}$ the family of definitional extensions $\left\{f(\vec{x})=t_{f}(\vec{x})\right\}_{f \in \chi}$, but $I$ makes those explicit extensions unnecessary.
2. Then, prove that $T_{\mathcal{E}} \models I(\psi)$ by standard inductive theorem proving methods, where $I(\psi)$ is the homomorphic extension of the theory interpretation $I$ to a formula $\psi$. If the choice of $I$ was correct, i.e., if indeed $T_{\mathcal{E}}=I(\psi)$, we can then think of $I$ as a witness, giving us a constructive proof of the existential formula $(\exists \chi) \psi$ for $T_{\mathcal{E}}$.
3. However, if some of the function symbols in $\chi$ are not definable as $\Sigma$-terms, then $e x$ tend $\mathcal{E}$ to a theory $\mathcal{E}^{\prime}$ (with auxiliary function symbols, and perhaps with auxiliary
sorts) that protects $T_{\mathcal{E}}$, i.e., such that $\left.T_{\mathcal{E}^{\prime}}\right|_{\Sigma} \cong T_{\mathcal{E}}$. Then, define $I$ as a theory interpretation $I: \chi \rightarrow \mathcal{E}^{\prime}$ and follow steps (1)-(2) above.
For any formula $(\exists \chi) \psi$ such that the function symbols in $\chi$ can be witnessed by computable functions in the initial algebra of interest $T_{\mathcal{E}}$ (which seems reasonable for many Computer Science applications and agrees with a constructive view of existential quantification), steps (1)-(3) above reduce - thanks to the Bergstra-Tucker Theorem- the theoremhood problem $T_{\mathcal{E}} \models(\exists \chi) \psi$ to the theoremhood problem $T_{\mathcal{E}}=I(\psi)$, with $I(\psi)$ a quantifier-free $\Sigma$-formula amenable to standard inductive theorem proving methods.

This of course does no guarantee that we can always prove the formula $I(\psi)$, even if the witness $I$ was correctly guessed. After all, our example theory $\mathcal{N}$ contains natural number addition and multiplication, so that, by Gödel's Incompleteness Theorem, there is no hope of having an inference system capable of proving all theorems in $T_{\mathcal{N}}$.

## 3 Multiclause-Based Inductive Theories and Induction Hypotheses

The syntax and semantics of the inductive logic, including the notions of multiclause and of inductive theory, are first presented in Section 3.1 Then, the important topic of how to effectively use induction hypotheses for conjecture simplification purposes is treated in Section 3.2

### 3.1 Multiclauses and Inductive Theories

Since predicate symbols can always be transformed into function symbols by adding a fresh new sort Pred, we can reduce all of order-sorted first-order logic to just reasoning about equational formulas whose only atoms are equations. Any quantifier-free formula $\phi$ can therefore be put in conjunctive normal form (CNF) as a conjunction of equational clauses $\phi \equiv \bigwedge_{i \in I} \Gamma_{i} \rightarrow \Delta_{i}$, where $\Gamma_{i}$, denoted $u_{1}=v_{1}, \cdots, u_{n}=v_{n}$, is a conjunction of equations $\bigwedge_{1 \leqslant i \leqslant n} u_{i}=v_{i}$ and $\Delta_{i}$, denoted $w_{1}=w_{1}^{\prime}, \cdots, w_{m}=w_{m}^{\prime}$, is a disjunction of equations $\bigvee_{1 \leqslant k \leqslant m} w_{k}=w_{k}^{\prime}$. Higher effectiveness can be gained by applying inductive inference rules not to a single clause, but to a conjunction of related clauses sharing the same condition $\Gamma$. Thus, we will assume that all clauses $\left\{\Gamma \rightarrow \Delta_{l}\right\}_{l \in L}$ with the same condition $\Gamma$ in the CNF of $\phi$ have been gathered together into a semantically equivalent formula of the form $\Gamma \rightarrow \bigwedge_{l \in L} \Delta_{l}$, which I will call a multiclause ${ }^{15}$ I will use the notation $\Lambda$ to abbreviate $\bigwedge_{l \in L} \Lambda_{l}$. Therefore, $\Lambda$ denotes a conjunction of disjunctions of equations. Multiclauses, of course, generalize clauses, which generalize both disjunctions of equations and conditional equations, which, in turn, generalize equations. Likewise, multiclauses generalize conjunctions of disjunctions of equations, which generalize conjunctions of equations, which generalize equations. Thus, multiclauses give us a very general setting for inductive reasoning.

What is an inductive theory? In an order-sorted equational logic framework, the simplest possible inductive theories we can consider are order-sorted conditional equational theories $\mathcal{E}=(\Sigma, E \cup B)$, where $E$ is a set of conditional equations (i.e., Horn clauses) of the form $u_{1}=v_{1}, \cdots, u_{n}=v_{n} \rightarrow w=w^{\prime}$, and $B$ is a set of equational axioms such as

[^10]associativity and/or commutativity and/or identity. Inductive properties are then properties satisfied in the initial algebra $T_{\mathcal{E}}$ associated to $\mathcal{E}$. Note that this is exactly the initial semantics of functional modules in the Maude language. So, as a first approximation, a Maude user can think of an inductive theory as an order-sorted functional module. The problem, however, is that as we perform inductive reasoning, the inductive theory of $\mathcal{E}$, let us denote it $[\mathcal{E}]$ to emphasize its initial semantics, needs to be extended by: (i) extra constants, and; (ii) extra formulas such as: (a) induction hypotheses, (b) lemmas, and (c) hypotheses associated to modus ponens reasoning. Thus, general inductive theories will have the form $[\bar{X}, \mathcal{E}, H]$, where $\bar{X}$ is a fresh set of constants having sorts in $\Sigma$ and $H$ is a set of $\Sigma(\bar{X})$ clauses ${ }^{16}$ corresponding to formulas of types (a)-(c) above. The models of an inductive theory $[\bar{X}, \mathcal{E}, H]$ are exactly the $\Sigma^{\square}(\bar{X})$-algebras $A$ such that $\left.A\right|_{\Sigma^{\square}} \cong T_{\mathcal{E}^{\square}}$ and $A=H$, where $\mathcal{E}^{\square}=\left(\Sigma^{\square}, E \cup B^{\square}\right)$ and $\Sigma^{\square}$ is the kind completion ${ }^{[7]}$ of $\Sigma$ defined in Section 2.6. Note that, since $\left.T_{\mathcal{E}^{\text {口 }}}\right|_{\Sigma}=T_{\mathcal{E}}$ [53], the key relation for reasoning is $\left.A\right|_{\Sigma} \cong T_{\mathcal{E}}$. Such algebras $A$ have a very simple description: they are pairs $\left(T_{\mathcal{E}^{\square}}, a\right)$ where $a: \bar{X} \rightarrow T_{\mathcal{E}}$ is the assignment interpreting constants $\bar{X}$. In Maude, such inductive theories $[\bar{X}, \mathcal{E}, H]$ can be defined as functional theories which protect the functional module $[\mathcal{E}]$, which in our expanded notation is identified with the inductive theory $[\varnothing, \mathcal{E}, \varnothing]$. I.e., $[\varnothing, \mathcal{E}, \varnothing]$ has no extra constants, hypotheses, lemmas, or assumptions. It is the inductive theory from which we will start our reasoning.

I will furthermore assume that $\overrightarrow{\mathcal{E}}=(\Sigma, B, \vec{E})$, with $B=B_{0} \uplus U$, is ground convergent, with a tota ${ }^{18} \mathrm{RPO}$ order $>$ modulo $B_{0}$ making $\overrightarrow{\mathcal{E}}_{U}$ operationally terminating, and that there is a "sandwich" $\left(\Omega, B_{\Omega}, \varnothing\right) \subseteq\left(\Sigma_{1}, B_{1}, \vec{E}_{1}\right) \subseteq(\Sigma, B, \vec{E})$ with $B_{\Omega} \subseteq B_{0}$ satisfying all the requirements in Section 2.8 including the sufficient completeness of $\overrightarrow{\mathcal{E}}$ w.r.t. $\Omega$, the finite variant property of $\mathcal{E}_{1}$, and the OS-compactness of $\left(\Omega, B_{\Omega}\right)$. Under the above assumptions, up to isomorphism, and identifying $T_{\mathcal{E}^{\square}}$ with $C_{\Sigma^{\square} / E, B}$, a model $(A, a)$ of an inductive theory $[\bar{X}, \mathcal{E}, H]$ has a very simple description as a pair $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$, where $\alpha: X \rightarrow T_{\Omega}$ is a ground constructor substitution, $[\alpha]$ denotes the composition $X \xrightarrow{\alpha} T_{\Omega} \xrightarrow{[-]} T_{\Omega / B_{\Omega}}$, with [-] the unique $\Omega$-homomorphism mapping each term $t$ to its $B_{\Omega}$-equivalence class $[t]$, and where $[\bar{\alpha}]: \bar{X} \rightarrow T_{\mathcal{E}^{\text {a }}}$ maps each $\bar{x} \in \bar{X}$ to $[\alpha](x)$, where $x \in X$ is the variable with same sort associated to $\bar{x} \in \bar{X}$. The fact that for each clause $\Gamma \rightarrow \Delta$ in $H$ we must have $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right) \models \Gamma \rightarrow \Delta$ has also a very simple expression. Let $Y=\operatorname{vars}(\Gamma \rightarrow \Delta)$. Then, $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right) \models \Gamma \rightarrow \Delta$ exactly means that $T_{\mathcal{E}^{\mathrm{a}}} \models(\Gamma \rightarrow \Delta)^{\circ} \alpha$, where $(\Gamma \rightarrow \Delta)^{\circ}$ is obtained

[^11]from $\Gamma \rightarrow \Delta$ by replacing each constant $\bar{x} \in \bar{X}$ appearing in it by its corresponding variable $x \in X$. Equivalently, it also means that for each ground constructor substitution $\beta: Y \rightarrow T_{\Omega}$ we have $T_{\mathcal{E}^{\square}}=(\Gamma \rightarrow \Delta)^{\circ}(\alpha \uplus \beta)$. This entire discussion can be summarized by the equivalence: $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right) \mid=\Gamma \rightarrow \Lambda$ iff $T_{\mathcal{E}^{\text { }}}=(\Gamma \rightarrow \Lambda)^{\circ} \alpha$. In particular, $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ is a model of the inductive theory $[\bar{X}, \mathcal{E}, H]$ iff $T_{\mathcal{E}^{\square}} \models H^{\circ} \alpha$.

We will finally assume that the clauses $H$ in an inductive theory $[\bar{X}, \mathcal{E}, H]$ have, first of all, been simplified with the theory $\overrightarrow{\mathcal{E}}_{\bar{X}_{U}}^{=}$that adds equationally-defined equality predicates to $\overrightarrow{\mathcal{E}}_{\bar{X}_{U}}$ (see Section 2.5), and then classified, according to a slightly refined version of the taxonomy described in Section 2.10, into the disjoint union $H=H_{e} \uplus H_{\vee, e} \uplus H_{n e}$, where: (i) $H_{e}$, the executable hypotheses, are (possibly conditional) equations that are either reductive (classes (1)-(2)), or usable unconditional or conditional equations (classes (3)-(4)) executable by ordered rewriting using the same RPO order $>$ modulo $B_{0}$ that makes $\overrightarrow{\mathcal{E}}=(\Sigma, B, \vec{E})$ ground convergent; (ii) $H_{\mathrm{v}, e}^{=}$, which we call the (=)-executable non-Horn hypotheses (because they can be executed as conditional $\Sigma^{=}$-rewrite rules, as explained below), are clauses of the form $\Gamma \rightarrow \Delta$ where $\Delta$ has more than one disjunct (therefore in class (6)) and such that $\operatorname{vars}(\Delta) \supseteq \operatorname{vars}(\Gamma)$; finally, $H_{n e}$, the non-executable hypotheses, are all other clauses in $H$ (necessarily in classes (5) or (6)). Although clauses in $H_{n e}$ cannot be used as rewrite rules to simplify conjectures, they can still be used for goal simplification in two other ways, namely, by means of the clause subsumption simplification rule (CS) and also (if in category (3)) in a user-guided manner by the equality rule (Eq), both described in Section4

### 3.2 Using Induction Hypotheses as Rewrite Rules

The effectiveness of an inductive inference system can be significantly increased by maximizing the ways in which induction hypotheses can be applied as rewrite rules to simplify inductive goals $\sqrt{19}$ In this regard, even for the most obvious canditates, namely, the equations $H_{e}$ in the above classification, which are easily orientable as rewrite rules $\vec{H}_{e}$ because they have either lefthand sides or candidate lefthand sides (when having two candidate lefthand sides, they are orientable as two $>$-constrained conditional rewrite rules: see Section 2.10, since such rules may contain operators enjoying unit axioms $U$ in $B=B_{0} \cup U$, we should not use $\vec{H}_{e}$ itself, but its $U$-transformation $\vec{H}_{e_{U}}$, which achieves modulo $B_{0}$ the same semantic effect as the rules $\vec{H}_{e}$ modulo $B=B_{0} \cup U$. A crucial reason for performing the $U$-transformation on such hypothesis rules is that we want to use the induction hypotheses not just for term simplification, but, more generally, for formula simplification. But since: (i) the rules in $\overrightarrow{\mathcal{E}}_{\bar{X}_{U}}^{=}$can simplify exactly the same $\Sigma$-terms as those in $\overrightarrow{\mathcal{E}}_{\bar{X}}$ (and to the same normal forms), but (ii) they can also simplify many QF $\Sigma$ formulas, we will always want to use the rules $\vec{H}_{e_{U}}$ together with the rules $\overrightarrow{\mathcal{E}}_{\bar{X}_{U}}^{=}$instead

[^12]of using the combination $\overrightarrow{\mathcal{E}}_{\bar{X}} \cup \vec{H}_{e}$, which is strictly weaker for formula simplification. How to most effectively do this, so as to maximize our chances to prove conjectures while avoiding non-termination problems is the matter I turn to next.

Note that formula simplification will always take place in the context of a goal associated to an inductive theory $[\bar{X}, \mathcal{E}, H]$. We can spell out how formula simplification will be achieved by describing such formula simplifications as the computations of an associated rewrite theory in the sense of Section 2.3 namely, the rewrite theory

$$
\mathcal{R}_{[\bar{X}, \mathcal{E}, H]}=\left(\Sigma^{=}(\bar{X}), E^{=} \cup B_{0}^{=}, \vec{H}_{e_{U}}^{+}\right)
$$

where -as already mentioned, and it will be further explained in what follows- the induction hypotheses $H$ have been suitably simplified beforehand to increase their effectiveness. The rewrite rules $\vec{H}_{e_{U}}^{+}=\vec{H}_{e_{U}} \cup \vec{H}_{\mathrm{V}, e_{U}}^{=}$are defined as follows:

1. $\vec{H}_{e_{U}}$ are the $U$-transformed rewrite rules corresponding to induction hypotheses in $H_{e}$. These are hypotheses orientable as either (possibly conditional) reductive rewrite rules, or as usable conditional equations, both oriented as background aware. In this case, the background equational theory is $\left(\Sigma^{=}(\bar{X}), E^{=} \cup B_{0}^{=}\right)$) and the usable equations are transformed $>$-constrained rewrite rules in the manner explained in Section 2.10 In both cases, if the rules are conditional -besides the possible variable matching condition $x:=r$ and constraint condition $l>x$ - their remaining conditional part will be either a conjunction of equations $\bigwedge_{i \in I} u_{i}=v_{i}$, or, for reductive or usable conditional equations in the cases (i)-(ii) discussed towards the end of Section 2.10, their remaining conditional part will be of the form $20 \bigwedge_{i \in I}\left(u_{i}=v_{i}\right) \rightarrow T$. In a rewrite theory $\mathcal{R}=(\Sigma, E \cup B, R)$, a rewrite condition $u \rightarrow v$ is evaluated for a given matching substitution $\theta$ by searching for a term $w$ such that: (i) either $u \theta=_{B} w$ or $u \theta \rightarrow_{R: E, B}^{+} w$, and (ii) there exists a substitution $\gamma$ such that $w={ }_{B}(v \gamma)$. In our case, this means that each rewrite condition $\left(u_{i}=v_{i}\right) \rightarrow \top$ will be evaluated by applying both the equational rules in $\vec{E}^{=}$, which include the rule $x=x \rightarrow \top$, and the rules in $\vec{H}_{e_{U}}^{+}$. This maximizes the chances of success when applying the rules in $\vec{H}_{e_{U}}$ to simplify a goal.
2. $\vec{H}_{\mathrm{v}, e_{U}}^{=}$are rules obtained from $U$-transformed hypotheses $\Gamma \rightarrow \Delta$ such that $\Delta$ contains two or more disjuncts and $\operatorname{vars}(\Gamma) \subseteq \operatorname{vars}(\Delta)$ as follows: (i) if $\Delta>u_{i}, v_{i}$ for each $u=v$ in $\Gamma$, where $>$ denotes the extension of the RPO order on $\Sigma$ to symbols in $\Sigma(X)^{=}$, then $\Gamma \rightarrow \Delta$ produces a rule of the form,

$$
\Delta \rightarrow \top \text { if } \bigwedge_{(u=v) \in \Gamma}(u=v) \rightarrow \top
$$

(ii) otherwise, $\Gamma \rightarrow \Delta$ produces a rule of the form,

$$
\Delta \rightarrow \top \text { if } \bigwedge_{(u=v) \in \Gamma} u=v
$$

A direct consequence of such a definition of $\mathcal{R}_{[\bar{X}, \varepsilon, H]}$ is that this theory is operationally terminating: we are guaranteed to never loop when simplifying a goal's formula with its associated rewrite theory $\mathcal{R}_{[\bar{X}, \mathcal{E}, H]}$. Operational termination of $\mathcal{R}_{[\bar{X}, \mathcal{E}, H]}$ means that each QF formula $\varphi$ will have a finite set of normal forms, which by abuse of notation will be denoted $\varphi!_{\vec{H}_{e_{U}}^{+}: \vec{E}_{U}^{=}, B_{0}}$. In Maude, such a set can be computed using the search command:

$$
\text { search } \varphi \Rightarrow!B: \text { NewBool }
$$

[^13]Two additional notational conventions will also be useful in what follows. We can identify within the set $\vec{H}_{e_{U}}$ the subset $\vec{H}_{g e_{U}} \subseteq \vec{H}_{e_{U}}$ of its ground unconditional $\Sigma(\bar{X})$-rewrite rules ${ }^{21}$ The second notational convention is related to the previous one. By definition, $\vec{H}_{e_{U}}^{\oplus}=\vec{H}_{e_{U}}^{+} \backslash \vec{H}_{g e_{U}}$. In a similar way, if our hypotheses $H$ before the $U$-transformation were classified as $H=H_{e} \uplus H_{\vee, e} \uplus H_{n e}$, and $H_{g e} \subseteq H_{e}$ denotes the ground equations, we define $H_{e}^{+}=H_{e} \uplus H_{\vee, e}$, and $H_{e}^{\oplus}=H_{e}^{+} \backslash H_{g e}$.

Simplifying Hypotheses. The above discussion has so far focused on how to effectively use induction hypotheses to simplify conjectures by rewriting, but who simplifies the simplifiers? There are, for example, two ways in which induction hypotheses may be ineffective as rewrite rules. To begin with, if the lefthand side of a hypothesis rule is not normalized by the rules in $\overrightarrow{\mathcal{E}}$, it may fail even to apply to a conjecture that has itself been simplified. Furthermore, induction hypotheses may preempt each other, in the sense that the application of one hypothesis might block the application of another, also useful, hypothesis. For a simple example, consider a ground hypothesis rule $\bar{x} \rightarrow \bar{y}$ and a nonground hypothesis rule $z+\bar{x} \rightarrow s(s(z))$. Then, application of the ground hypothesis to an expression $u+\bar{x}$ will preempt application of the non-ground hypothesis.

We can try to minimize these problems by: (i) ensuring that lefthand sides of hypotheses used as rewrite rules (or even as non-executable hypotheses) are $\vec{E}, B$-normalized, and (ii) trying to minimize in a practical way the problem of executable hypotheses preempting each other. These aims can be advanced by a hypothesis transformation process $H \mapsto H_{\text {simp }}$ that tries to arrive at simplified hypotheses $H_{\text {simp }}$ meeting goals (i)-(ii) as much as possible in a practical manner.

There is, of course, no single such transformation possible. What follows is a first proposal for such a transformation, open to further modifications and improvements through future experimentation. The transformation $H \mapsto H_{\text {simp }}$ is defined as follows:

1. We first define $H^{\prime}=\operatorname{clauses}\left(H!_{\vec{\varepsilon}_{\overline{\bar{x}_{U}}}}\right)$ where clauses turns a formula into a set of clauses. For example, if $[,,-]$ is a constructor for unordered pairs, $\vec{E}=$ will contain a rule $[x, y]=\left[x^{\prime}, y^{\prime}\right] \rightarrow\left(x=x^{\prime}\right) \wedge\left(y=y^{\prime}\right)$. Then, assuming that the equation $[u, v]=\left[u^{\prime}=v^{\prime}\right]$ belongs to $H$, and that the $u, u^{\prime}, v, v^{\prime}$ are already in $\vec{E}, B$-normal form, we will have
 two equations $u=u^{\prime}$ and $v=v^{\prime}$ will be more widely applicable as induction hypothesis than the original equation $[u, v]=\left[u^{\prime}=v^{\prime}\right]$.
2. As usual, we can classify $H^{\prime}$ as the disjoint union $H^{\prime}=H_{g e}^{\prime} \uplus H_{e}^{\oplus} \uplus H_{n e}^{\prime}$. We then define $H_{\text {simp }}=H^{\prime \prime}$, where,
3. $H_{g e}^{\prime \prime}=$ orient $_{>}\left(\left(c c_{B_{0}}^{>}\left(H_{g e}^{\prime}\right)\right)!_{\vec{E}, B}\right)$. That is, we first compute the congruence closure modulo $B_{0}$ of the ground equations $H_{g e}^{\prime}$ (or an approximation to it if $B_{0}$ contains axioms for associative but non-commutative operators) to make them convergent; but to exclude the possibility that some resulting rules might not be $\vec{E}, B$-normalized, we further $\vec{E}, B$-normalize both sides of those ground equations and orient them again as rules with the RPO order $>$.

[^14]4. ${H_{e}^{\prime \prime}}^{\oplus}$ is generated as follows: (i) For each $u=v$ if cond in $H_{e}^{(\oplus}$ (where cond could be empty) we add to $H_{e}^{\prime \prime \oplus}$ the set $(u=v)!_{\vec{H}_{g e}^{\prime \prime}: \vec{E}, B}$ if cond. Please, recall the notation $\rightarrow_{R: \vec{E}, B}$ introduced in Section 2.3 for rewriting with the rules $R$ and equations $E$ of a rewrite theory modulo axioms $B$. Since confluence is not guaranteed, $(u=v)!_{\vec{H}_{g:}^{\prime \prime}, \vec{E}, B}$ if cond may in general be a set of hypotheses. (ii) For each $\Gamma \rightarrow \Delta$ in $H^{\prime \oplus}$ we add to $H_{e}^{\prime \prime \oplus}$ the set $\Gamma \rightarrow(\Delta)!_{\vec{H}_{g e}^{\prime \prime}: \vec{E}, B}$.
5. $H_{n e}^{\prime \prime}$ is generated by adding for each clause (which could be a conditional equation) $\Gamma \rightarrow \Delta$ in $H_{n e}^{\prime}$ the set $(\Gamma \rightarrow \Delta)!_{\vec{H}_{g e}^{\prime \prime}: \vec{E}, B}$, to $H_{n e}^{\prime \prime}$.
The simplified hypotheses $H^{\prime \prime}$ thus obtained, give rise to corresponding rewrite rules $\vec{H}_{g e}^{\prime \prime} \uplus{\overrightarrow{H^{\prime \prime}}}_{e U}^{\oplus}$ and to non-executable hypotheses $H_{n e}^{\prime \prime}$ as usual. So, what has been achieved by the $H \mapsto H_{\text {simp }}$ transformation thus defined? The main achievements are: (1) the ground rewrite rules $\vec{H}_{g e}^{\prime \prime}$ are $\vec{E}, B$-normalized and, with some luck, these rules may even be convergent; (2) the rewrite rules in ${\overrightarrow{H^{\prime \prime}}}_{e U}^{\oplus}$ are both $\vec{E}, B$-normalized and $\vec{H}_{g e}^{\prime \prime}, B$-normalized; and (3) the consequents of clauses in $H_{n e}^{\prime \prime}$ are likewise both $\vec{E}, B$-normalized and $\vec{H}_{g e}^{\prime \prime}, B$ normalized. Although the clauses in $H_{n e}^{\prime \prime}$ are not executable as rewrite rules, as we shall see, they can nevertheless simplify goals by means of either the clause subsumption CS or the EQ rule, both discussed in Section 4 Since the $\mathbf{C S}$ and $\mathbf{E Q}$ rules will be applied by matching a goal (resp. a term in the goal) (that can both be safely assumed to already be both $\vec{E}, B$-normalized and $\vec{H}_{g e}^{\prime \prime}, B$-normalized) to a pattern hypothesis in $H_{n e}^{\prime \prime}$ (resp. to a chosen side of the equation), the chances for such a matching to succeed are maximized by the above definition of $H_{n e}^{\prime \prime}$.

## 4 Inductive Inference System

The inductive inference system presented below transforms inductive goals of the form $[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda$, where $[\bar{X}, \mathcal{E}, H]$ is an inductive theory and $\Gamma \rightarrow \Lambda$ is a $\Sigma^{\square}(\bar{X})$ multiclause, into sets of goals. The empty set of goals is denoted $T$ to suggests that the goal from which it was generated has been proved (is a closed goal). However, in the special case of goals of the form $[\varnothing, \mathcal{E}, \varnothing] \Vdash \Gamma \rightarrow \Lambda$, called initial goals, we furthermore require that $\Gamma \rightarrow \Lambda$ is a $\Sigma$-multiclause; and we also allow existential initial goals of the form $[\varnothing, \mathcal{E}, \varnothing] \Vdash(\exists \chi)(\Gamma \rightarrow \Lambda)$, with $\chi$ a Skolem signature and $\Gamma \rightarrow \Lambda$ a $\Sigma \cup \chi$-multiclause (see Section 2.11).

A proof tree is a tree of goals, where at the root we have the original goal that we want to prove and the children of each node in the tree have been obtained by applying an inference rule in the usual bottom-up proof search fashion. Goals in the leaves are called the pending goals. A proof tree is closed if it has no pending goals, i.e., if all its leaves are marked $T$. Soundness of the inference system means that if the goal $[\bar{X}, \mathcal{E}, H] \Vdash \phi$ is the root of a closed proof tree, then $\phi$ is valid in the inductive theory $[\bar{X}, \mathcal{E}, H]$, i.e., it is satisfied by all the models $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ of $[\bar{X}, \mathcal{E}, H]$ in the sense explained above.

The inductive inference system presented below consists of two sets of inference rules: (1) goal simplification rules, which are easily amenable to automation, and (2) inductive rules, which are usually applied under user guidance, although they could also be automated by tactics.

To increase its effectiveness, this inference system maintains the invariant that the induction hypotheses $H$ in all inductive theories will always be in simplified form.

### 4.1 Goal Simplification Rules

## Equality Predicate Simplification (EPS).

$$
\frac{\left\{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma_{i}^{\prime} \rightarrow \Lambda_{i}^{\prime}\right\}_{i \in I}}{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda}
$$

where $\left(\bigwedge_{i \in I} \Gamma_{i}^{\prime} \rightarrow \Lambda_{i}^{\prime}\right) \in(\Gamma \rightarrow \Lambda)!{\overrightarrow{\vec{C}_{\overline{\bar{x}_{U}}}} \cup_{\vec{H}_{e U}^{+}}^{+} \text {. Furthermore, if } T \in(\Gamma \rightarrow \Lambda)!\overrightarrow{\mathcal{E}}_{\overline{\bar{X}}_{U}} \cup \vec{H}_{e_{U}}^{+}}$, then $\bigwedge_{i \in I} \Gamma_{i}^{\prime} \rightarrow \Lambda_{i}^{\prime}$ is chosen to be $T$; if $\perp \in(\Gamma \rightarrow \Lambda)!{\overrightarrow{\varepsilon_{\overline{\bar{x}}}^{U}}}^{\cup}{\overrightarrow{H_{e U}}}_{+}^{+}$, then $\bigwedge_{i \in I} \Gamma_{i}^{\prime} \rightarrow \Lambda_{i}^{\prime}$ is chosen to be $\perp$ (i.e., the conjecture $\Gamma \rightarrow \Lambda$ is then shown to be false); otherwise, the choice of $\bigwedge_{i \in I} \Gamma_{i}^{\prime} \rightarrow \Lambda_{i}^{\prime}$ is unspecified, but it should be optimized according to some criteria that make the resulting subgoals easier to prove ${ }^{22}$ The fact that an EPS simplification might result in a conjunction of goals is illustrated in Example 3 below. We assume that the hypotheses $H$ have already been simplified using the $H \mapsto H_{\text {simp }}$ transformation, since this should be an invariant maintained throughout. We also assume that constructors in the transformed theory $\mathcal{E}_{U}$ are free modulo axioms ${ }^{23}$ This means that in $\mathcal{E}_{\Omega}=\left(\Omega, B_{\Omega}\right)$, the axioms $B_{\Omega}$ decompose as $B_{\Omega}=Q_{\Omega} \uplus U_{\Omega}$ with $U_{\Omega}$ the unit axioms and $Q_{\Omega}$ the associative and/or commutative axioms such that $T_{\mathcal{E}_{\Omega}} \cong T_{\Omega / Q_{\Omega}}$. This can be arranged with relative ease in many cases by subsort overloading, so that the rules in $\vec{U}_{\Omega}$ only apply to subsort-overloaded operators that are not constructors.

For example, consider sorts Elt $<$ NeList $<$ List and $\Omega$ with operators nil of sort List and _; : NeList NeList $\rightarrow$ NeList and $B_{\Omega}$ associativity of _; with identity nil, but where $\__{-}$_ : List List $\rightarrow$ List, declared with the same axioms, is in $\Sigma \backslash \Omega$. Then $Q_{\Omega}$ is just the associativity axiom for (_;-).

In summary, this inference rule simplifies a multiclause $\Gamma \rightarrow \Lambda$ with: (i) the rules in $\overrightarrow{\mathcal{E}}_{U}$, (ii) the equality predicate rewrite rules in $\overrightarrow{\mathcal{E}}_{U}^{=}$, and (iii) the hypothesis rewrite rules $\vec{H}_{e_{U}}^{+}{ }^{24}$

Example 3. Let $\mathcal{N} \mathcal{P}$ denote theory of the natural numbers in Peano notation with the usual equations defining addition, + , multiplication, $*$, and exponentiation, $(-)^{(-)}$, and with two additional sorts, Pair and UPair, of, respectively, ordered and unordered pairs of numbers, built with the constructor operators, [-, ] : Nat Nat $\rightarrow$ Pair and $\{,,-\}:$ Nat Nat $\rightarrow$ UPair, where $\left\{{ }_{-,}\right\}$satisfies the commutativity axiom. Now consider the goal:

$$
[\varnothing, \mathcal{N} \mathcal{P}, \varnothing] \Vdash\left\{x^{s(s(0))}, y\right\}=\{s(y), 0\} \rightarrow\left[x+x^{s(s(0))}, x * x\right]=[s(x+y), x]
$$

Note that the theory $\overrightarrow{\mathcal{N P}}^{=}$includes, among others, the rules:

[^15]- $[x, y]=\left[x^{\prime}, y^{\prime}\right] \rightarrow x=x^{\prime} \wedge y=y^{\prime}$
- $\{x, y\}=\left\{x^{\prime}, y^{\prime}\right\} \rightarrow\left(x=x^{\prime} \wedge y=y^{\prime}\right) \vee\left(x=y^{\prime} \wedge y=x^{\prime}\right)$
$-s(x)=x \rightarrow \perp$.
Application of the first and second $\overrightarrow{\mathcal{N P}}{ }^{=}$-rules to the above clause, plus Boolean simplification, plus the equations for $+, *,()^{(-)}$, gives us a conjunction of two multiclauses:

$$
x * x=s(y), y=0 \rightarrow x+(x * x)=s(x+y) \wedge x * x=x
$$

and

$$
x * x=0, y=s(y) \rightarrow x+(x * x)=s(x+y) \wedge x * x=x .
$$

But, since $y=s(y)$ simplifies to $\perp$ by the third rule, the second multiclause simplifies to T. So we just get the first multiclause as the result of applying the EPS rule to our original goal.

## Constructor Variant Unification Left (CVUL).

$$
\frac{\left\{\left[\bar{X} \uplus \bar{Y}_{\alpha}, \mathcal{E},\left(\left.H \cup \tilde{\bar{\alpha}}\right|_{\bar{X}_{\Gamma}}\right)_{\operatorname{simp}}\right] \Vdash\left(\Gamma^{\prime} \rightarrow \Lambda\right) \bar{\alpha}\right\}_{\alpha \in U n i f}^{\mathcal{\varepsilon}_{1}}\left(\Gamma^{\circ}\right)}{}
$$

where: (i) $\Gamma$ is a conjunction of $\mathcal{E}_{1}$-equalities and $\Gamma^{\prime}$ does not contain any $\mathcal{E}_{1}$-equalities; (ii) $\bar{X}_{\Gamma}$ is the (possibly empty) set of constants from $\bar{X}$ appearing in $\Gamma$, and $X_{\Gamma}$ the set of variables obtained by replacing each $\bar{x} \in \bar{X}_{\Gamma}$ by a fresh variable $x$ of the same sort; (iii) $\Gamma^{\circ}$ is just $\Gamma\{\bar{x} \mapsto x\}_{\bar{x} \in \bar{X}_{\Gamma}}$, i.e., we replace each constant $\bar{x} \in \bar{X}_{\Gamma}$ by its corresponding variable $x \in X_{\Gamma}$ (this makes possible treating the constants in $\bar{X}_{\Gamma}$ as variables for unification purposes); (iv) $Y=\operatorname{ran}(\alpha)$ is a set of fresh variables, $Y_{\alpha} \subseteq Y$ is, by definition, the set of variables $Y_{\alpha}=\operatorname{vars}\left(\alpha\left(X_{\Gamma}\right)\right)$, and $\bar{Y}_{\alpha}$ is the corresponding set of constants, where each $y \in Y_{\alpha}$ is replaced by a fresh constant $\bar{y}$ of the same sort; (v) $\bar{\alpha}$ is the composed substitution $\bar{\alpha}=\{\bar{x} \mapsto x\}_{\bar{x} \in \bar{X}_{I}} \alpha\{y \mapsto \bar{y}\}_{y \in Y_{\alpha}}$; (vi) $\left.\widetilde{\bar{\alpha}}\right|_{\bar{X}_{\Gamma}}$ is the set of ground equations $\left.\tilde{\bar{\alpha}}\right|_{\bar{X}_{\Gamma}}=\{\bar{x}=$ $\bar{\alpha}(\bar{x})\}_{\bar{x} \in \bar{X}_{\Gamma}}$; and (vii) Unif $\mathcal{E}_{\mathcal{E}_{1}}^{\Omega}\left(\Gamma^{\circ}\right)$ denotes the set of constructor $\mathcal{E}_{1}$-unifiers of $\Gamma^{\circ}$ [54770].

The CVUL simplification rule can be very powerful. The most powerful case is when $U_{n i} \int_{\mathcal{E}_{1}}^{\Omega}\left(\Gamma^{\circ}\right)=\varnothing$, since then there are no subgoals, i.e., the rule's premise becomes $T$, and we have proved the given goal.

The main reason for the extra technicalities (i)-(viii) is that they make this simplification rule more generally applicable, so that it can also be applied when $\Gamma$ contains some extra constants in $\bar{X}$. However, extra care is required to make sure that the CVUL rule remains sound in this more general setting. The main idea is to turn such extra constants into variables. But in fact they are constants. What can we do? That is what the technicalities (i)-(viii), and in particular the new ground hypotheses $\left.\widetilde{\bar{\alpha}}\right|_{\bar{X}_{r}}$, answer. Since a concrete example is worth a thousand generic explanations, let us see the technicalities (i)-(viii) at work in a simple example.

Example 4. Consider an equational theory $\mathcal{E}$ containing the multiset specification in Example 1 in Section 2.9 and perhaps many more things. For our purposes here, let us assume that it also includes a Boolean predicate $p:$ MSet $\rightarrow$ Bool whose defining equations are irrelevant here. The theory $\mathcal{E}$ certainly has an FVP subtheory $\mathcal{E}_{1} \subseteq \mathcal{E}$ which contains the subsort-overloaded $A C$ multiset union operator $\cup_{\_}$, and a single equation,
namely, $S \cup \varnothing=S$, oriented as the rule $S \cup \varnothing \rightarrow S$, with $S$ of sort $M S e t$. Now consider the inductive goal:

$$
x \cup \bar{U}=y \cup V \rightarrow p(V)=\text { true } .
$$

where $x, y$ have sort $E l t, V$ has sort $N e M S e t$, and the constant $\bar{U}$ has also sort NeMSet. So in this example our $\Gamma$ is $x \cup \bar{U}=y \cup V, \bar{X}_{\Gamma}=\{\bar{U}\}, X_{\Gamma}=\{U\}$, which we assume is fresh, i.e., it appears nowhere else, and $\Gamma^{\circ} \equiv x \cup U=y \cup V$. One of the variant constructor unifiers of $\Gamma^{\circ}$ is the unifier $\alpha=\left\{U \mapsto y^{\prime} \cup W, x \mapsto x^{\prime}, y \mapsto y^{\prime}, V \mapsto x^{\prime} \cup W\right\} . Y_{\alpha}=\operatorname{vars}\left(\alpha\left(X_{\Gamma}\right)\right)=$ $\operatorname{vars}(\alpha(U))=\left\{y^{\prime}, W\right\}$, and $\bar{Y}_{\alpha}=\left\{\overline{y^{\prime}}, \bar{W}\right\}$. Therefore, $\bar{\alpha}$ is the composed substitution:

$$
\{\bar{U} \mapsto U\}\left\{U \mapsto y^{\prime} \cup W, x \mapsto x^{\prime}, y \mapsto y^{\prime}, V \mapsto x^{\prime} \cup W\right\}\left\{y^{\prime} \mapsto \overline{y^{\prime}}, W \mapsto \bar{W}\right\} .
$$

That is, the substitution $\bar{\alpha}=\left\{\bar{U} \mapsto \overline{y^{\prime}} \cup \bar{W}, x \mapsto x^{\prime}, y \mapsto \overline{y^{\prime}}, V \mapsto x^{\prime} \cup \bar{W}\right\}$, and $\left.\widetilde{\bar{\alpha}}\right|_{\bar{X}_{\Gamma}}=\left\{\bar{U}=\overline{y^{\prime}} \cup \bar{W}\right\}$. Therefore, if our original goal had the form:

$$
[\bar{X}, \mathcal{E}, H] \Vdash x \cup \bar{U}=y \cup V \rightarrow p(V)=\text { true }
$$

then the subgoal associated to the constructor variant unifier $\alpha$ is:

$$
\left[\bar{X} \uplus \bar{Y}_{\alpha}, \mathcal{E},\left(H \cup\left\{\bar{U}=\overline{y^{\prime}} \cup \bar{W}\right\}\right)_{\text {simp }}\right] \Vdash(p(V)=\text { true }) \bar{\alpha}
$$

That is, the subgoal:

$$
\left[\bar{X} \uplus \bar{Y}_{\alpha}, \mathcal{E},\left(H \cup\left\{\bar{U}=\overline{y^{\prime}} \cup \bar{W}\right\}\right)_{\text {simp }}\right] \Vdash p\left(x^{\prime} \cup \bar{W}\right)=\text { true } .
$$

Note the very useful, but slight poetic license of disregarding any differences between (universal) Skolem constants and variables in this extended notation for substitutions.

## Constructor Variant Unification Failure Right (CVUFR).

$$
\frac{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda \wedge \Delta}{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda \wedge(u=v, \Delta)}
$$

where $u=v$ is a $\mathcal{E}_{1_{\bar{X}}}$-equality and $\operatorname{Uni} f_{\mathcal{E}_{1}}^{\Omega}\left((u=v)^{\circ}\right)=\varnothing$.
Substitution Left (SUBL).
We consider two cases: when $x$ is a variable, and when $\bar{x}$ is a fresh constant.

$$
\frac{[\bar{X}, \mathcal{E}, H] \Vdash(\Gamma \rightarrow \Lambda)\{x \mapsto u\}}{[\bar{X}, \mathcal{E}, H] \Vdash x=u, \Gamma \rightarrow \Lambda}
$$

where: (i) $x$ is a variable of sort $s, l s(u) \leqslant s$, and $x \notin \operatorname{vars}(u)$; and (ii) $u$ is not a $\Sigma_{1}$-term and $\Gamma$ contains no other $\Sigma_{1}$-equations. Note that ${ }_{-}=$is assumed commutative, so cases $^{\text {a }}$ $x=u$ and $u=x$ are both covered.

When $\bar{x}$ is a fresh constant the SUBL rule has the form:

$$
\frac{\left[\bar{X} \uplus \bar{Y}_{u}, \mathcal{E},(H \cup\{\bar{x}=\bar{u}\})_{s i m p}\right] \Vdash(\Gamma \rightarrow \Lambda)\left(\{y \mapsto \bar{y}\}_{y \in Y_{u}} \uplus\{\bar{x} \mapsto \bar{u}\}\right)}{[\bar{X}, \mathcal{E}, H] \Vdash \bar{x}=u, \Gamma \rightarrow \Lambda}
$$

where $\bar{x} \in \bar{X}$ has sort $s, l s(u) \leqslant s, \bar{x}$ does not appear in $u$, which is not a $\Sigma_{1}$-term, and $\Gamma$ contains no $\Sigma_{1}$-equations; and where $Y_{u}=\operatorname{vars}(u), \bar{Y}_{u}$ are fresh new constants $\bar{y}$ of same sort for each $y \in Y_{u}$, and $\bar{u} \equiv u\{y \mapsto \bar{y}\}_{y \in Y_{u}}$. Note again that ${ }_{-}={ }_{\_}$is assumed commutative.

Substitution Right (SUBR).
We again consider two cases: when $x$ is a variable, and when $\bar{x}$ is a fresh constant.

$$
\frac{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow x=u \quad[\bar{X}, \mathcal{E}, H] \Vdash(\Gamma \rightarrow \Lambda)\{x \mapsto u\}}{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda \wedge x=u}
$$

 looping, and (ii) makes $\{x \mapsto u\}$ an order-sorted substitution. Cases $x=u$ and $u=x$ are both covered.

When $\bar{x}$ is a fresh constant the SUBR rule has the form:

$$
\frac{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \bar{x}=u \quad\left[\bar{X} \uplus \bar{Y}_{u}, \mathcal{E},(H \cup\{\bar{x}=\bar{u}\})_{s i m p}\right] \Vdash(\Gamma \rightarrow \Lambda)\left(\{y \mapsto \bar{y}\}_{y \in Y_{u}} \uplus\{\bar{x} \mapsto \bar{u}\}\right)}{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda \wedge \bar{x}=u}
$$

provided (i) $\Lambda \neq \mathrm{T}$, (ii) $\bar{x} \in \bar{X}$ has sort $s$ and $l s(u) \leqslant s$, and (iii) $\bar{x}$ does not appear in $u$; and where $Y_{u}=\operatorname{vars}(u), \bar{Y}_{u}$ are fresh new constants $\bar{y}$ of same sort for each $y \in Y_{u}$, and $\bar{u} \equiv u\{y \mapsto \bar{y}\}_{y \in Y_{u}}$. Cases $\bar{x}=u$ and $u=\bar{x}$ are both covered.

## Narrowing Simplification (NS).

$$
\frac{\left\{\left[\bar{X}_{\uplus} \bar{Y}_{i, j}, \mathcal{E},\left(\left.H \uplus \tilde{\bar{\alpha}}_{i, j}\right|_{\bar{f}_{f(f)}}\right)_{\operatorname{simp} p}\right] \Vdash\left(\Gamma_{i},(\Gamma \rightarrow \Lambda)\left[r_{i}=u\right]_{p}\right) \bar{\alpha}_{i, j} j_{i \in I_{0}}^{j \in J_{i}}\right.}{[\bar{X}, \mathcal{E}, H] \Vdash(\Gamma \rightarrow \Lambda)[f(\vec{v})=u]_{p}}
$$

where:

1. $f(\vec{v})$ is called the narrowex of goal $\Gamma \rightarrow \Lambda$ for the equation at position $p, \bar{X}_{f(\vec{v})}$ is the set of constants from $\bar{X}$ appearing in $f(\vec{v}), X_{f(\vec{v})}$ are the corresponding fresh variables $x$ having the same sort as $\bar{x}$ for each $\bar{x} \in \bar{X}_{f(\vec{v})}$, and $f(\vec{v})^{\circ}$ is the term obtained by simultaneously replacing each $\bar{x} \in \bar{X}_{f(\vec{v})}$ by its corresponding $x \in X_{f(\vec{v})}$.
2. $f$ is a non-constructor symbol in $\Sigma \backslash \Omega$, the terms $\vec{v}$ are $\Omega$-terms, and $f$ is defined in the transformed ground convergent theory $\overrightarrow{\mathcal{E}}_{U}$ by a family of (possibly conditional) rewrite rules (with constructor argument subcalls), of the form: $\left\{[i]: f\left(\vec{u}_{i}\right) \rightarrow\right.$ $r_{i}$ if $\left.\Gamma_{i}\right\}_{i \in I}$ such that: (i) are renamed with fresh variables disjoint from those in $X_{f(\vec{v})}$ and in $\Gamma \rightarrow \Lambda$; (ii) as assumed throughout, for each $i \in I, \operatorname{vars}\left(f\left(\vec{u}_{i}\right)\right) \supseteq \operatorname{vars}\left(r_{i}\right) \cup$ $\operatorname{vars}\left(\Gamma_{i}\right)$ and the rules are sufficiently complete, i.e., can rewrite modulo the axioms $B_{0}$ of $\overrightarrow{\mathcal{E}}_{U}$ any $\Sigma$-ground term of the form $f(\vec{w})$, with the $\vec{w}$ ground $\Omega$-terms; and (iii) are the transformed rules by the $\overrightarrow{\mathcal{E}} \mapsto \overrightarrow{\mathcal{E}}_{U}$ transformation of corresponding rules defining $f$ in $\overrightarrow{\mathcal{E}}$ and are such that, as explained in Footnote 9 they never lose their lefthandside's top symbol $f$ in the $\overrightarrow{\mathcal{E}} \mapsto \overrightarrow{\mathcal{E}}_{U}$ transformation due to a $U$-collapse.
3. For each $i \in I$, $\operatorname{Unif}_{B_{0}}\left(f(\vec{v})^{\circ}=f\left(\vec{u}_{i}\right)\right)$ is a family of most general $B_{0}$-unifier ${ }^{[25}$ $\operatorname{Unif}_{B_{0}}\left(f(\vec{v})^{\circ}=f\left(\overrightarrow{u_{i}}\right)\right)=\left\{\alpha_{i, j}\right\}_{j_{J_{i}}}$, with $I_{0}=\left\{i \in I \mid\right.$ Unif $\left._{B_{0}}\left(f(\vec{v})^{\circ}=f\left(\overrightarrow{u_{i}}\right)\right) \neq \varnothing\right\}$,

[^16]and with $\operatorname{dom}\left(\alpha_{i, j}\right)=\operatorname{vars}(f(\vec{v}))^{\circ} \uplus \operatorname{vars}\left(f\left(\vec{u}_{i}\right)\right), \operatorname{ran}\left(\alpha_{i, j}\right)$ is a set of fresh variables not appearing anywhere, $Y_{i, j}=\operatorname{vars}\left(\alpha_{i, j}\left(X_{f(\vec{v})}\right)\right)$, and $\bar{Y}_{i, j}$ the set of fresh constants $\bar{y}$ of same sort for each variable $y \in Y_{i, j}$, and $\bar{\alpha}_{i, j}$ the composed substitution $\bar{\alpha}_{i, j}=\{\bar{x} \mapsto x\}_{\bar{x} \in \bar{X}_{f(\bar{v})}} \alpha_{i, j}\{y \mapsto \bar{y}\}_{y \in Y_{i, j}}$. Finally, $\left.\widetilde{\bar{\alpha}}_{i, j}\right|_{\bar{X}_{f(\vec{v})}}$ is the set of ground equations $\left.\widetilde{\bar{\alpha}}_{i, j}\right|_{\bar{X}_{f(\bar{v})}}=\left\{\bar{x}=\bar{\alpha}_{i, j}(\bar{x})\right\}_{\bar{x} \in \bar{X}_{f(\overrightarrow{)}}}$.
4. We furthermore assume that: (i) $u$ is a $\Sigma_{1}$-term; and (ii) all $r_{i}$ in the set of equations $\left\{[i]: f\left(\vec{u}_{i}\right) \rightarrow r_{i} \text { if } \Gamma_{i}\right\}_{i \in I}$ defining $f$ are also $\Sigma_{1}$-terms, and $f$ is not a $\Sigma_{1}$-symbol. This will ensure that the equations $\left(r_{i}=u\right) \bar{\alpha}_{i, j}$ are all $\Sigma_{1}$-equations. As earlier, we assume throughout that the symbol $\quad=\_$is commutative.

Thanks to condition (4), the effect of this rule if $p$ is a position in the premise $\Gamma$ of the goal multiclause is that the CVUL simplification rule will become enabled in all the resulting subgoals, thus generating a healthy "chain reaction" of simplifications. Given the more restrictive nature of the CVUFR rule, the effect will be more limited if $p$ is a position in the multiclause's conclusion $\Lambda$. The intention to ensure some definite progress in the simplification process is the only reason for adding condition (4) as a reasonable restriction for automation. However, the NS rule makes perfect sense dropping such a restriction, i.e., as a simplification rule of the form:

$$
\frac{\left\{\left[\bar{X}_{\uplus} \bar{Y}_{i, j}, \mathcal{E},\left(\left.H \uplus \overline{\bar{\alpha}}_{i, j}\right|_{\bar{X}_{f(\vec{r})}}\right)_{\operatorname{simp}}\right] \Vdash\left(\Gamma_{i},(\Gamma \rightarrow \Lambda)\left[r_{i}\right]_{p}\right) \bar{\alpha}_{i, j}\right\}_{i \in I_{0}}^{j \in J_{i}}}{[\bar{X}, \mathcal{E}, H] \Vdash(\Gamma \rightarrow \Lambda)[f(\vec{v})]_{p}}
$$

keeping the above side conditions (1)-(3), but now allowing the narrowex $f(\vec{v})$ to apear anywhere in $\Gamma \rightarrow \Lambda$. In particular, $f(\vec{v})$ may well be a proper subterm of another $\Sigma$-term, and therefore neither the lefthand nor the righthand side of an equation. For purposes of proving soundness, we will use this more general form of the NS inference rule. In practice, we shall regard NS as a simplification rule with a dual use: (i) automated with the additional restrictions in (4), and (ii) applied under user control with the more general rule, assuming (1)-(3).

The NS simplification rule is very closely related, and complements, the narrowing induction (NI) inference rule to be discussed later. The only differences are that: (i) NI adds additional induction hypotheses to its subgoals, based on the subcalls appearing in the rules defining $f$; and (ii) in the NI rule, the narrowex $f(\vec{v})$ does not have any constants in $\bar{X}$. Therefore, these rules have different restrictions and can cover different situations. Since several detailed examples illustrating the use of the NI rule will be given later, and the notation introduced in both rules is quite similar, I do not give an example here.

## Clause Subsumption (CS).

$$
\frac{[\bar{X}, \mathcal{E}, H \cup\{\Gamma \rightarrow \Delta\}] \Vdash \Gamma^{\prime} \rightarrow(E S C) \theta}{[\bar{X}, \mathcal{E}, H \cup\{\Gamma \rightarrow \Delta\}] \Vdash \Gamma^{\prime} \rightarrow \Lambda^{\prime}}
$$

of generality, that all the lefthand sides $f\left(\overrightarrow{u_{i}}\right)$ of the rules defining $f$ are linear terms (have no repeated variables); because if they are not, we can easily linearize them and add the associated equalities between the linearized variables to their rule's condition $\Gamma_{i}$.
where $\theta$ is a matching (modulo $A C U$ ) substitution such that $\Gamma^{\prime} \rightarrow \Lambda^{\prime}={ }_{B}=\left(\Gamma, E S \rightarrow \Delta, E S^{\prime} \wedge\right.$ $E S C) \theta$. That is, the hypothesis $\Gamma \rightarrow \Delta$ is extended to the pattern $\Gamma, E S \rightarrow \Delta, E S^{\prime} \wedge E S C$ for pattern matching multiclauses, where the variables $E S$ and $E S^{\prime}$ range over equation sets (with $E S$, appearing on the left side, understood as a conjunction, and $E S^{\prime}$, appearing on the right side, understood as a disjunction), and the variable ESC ranges over equation set conjunctions (with such equation sets understood as disjunctions).

This rule can be fully automated: if a substitution $\theta$ is found such that the goal matches the extended pattern of some hypothesis $\Gamma \rightarrow \Delta$ in the goal's inductive theory, then the goal can be automatically simplified.

Let us illustrate the CS rule by means of a simple example. Suppose that the inductive theory involves the Peano natural numbers with $0, s,+, *$ and $>$, the goal formula is: $\Gamma^{\prime} \rightarrow \Delta^{\prime} \equiv$ true $=s(n)>m$, true $=m>\bar{z}, m * m=m \rightarrow s(n)>\bar{z}=$ true $\wedge(n * n=n, n>m=$ true $)$ and we have the (non-executable in this case) hypothesis:

$$
\Gamma \rightarrow \Delta \equiv x>y=\text { true }, y>\bar{z}=\text { true } \rightarrow x>\bar{z}=\text { true }
$$

Then, the CS rule can be applied with matching substitution $\theta=\{x \mapsto s(n), y \mapsto m, E S \mapsto$ $(m * m=m), E S^{\prime} \mapsto \varnothing, E S C \mapsto(n * n=n, n>m=$ true $\left.)\right\}$, and yields the resulting subgoal:

$$
\Gamma^{\prime} \rightarrow \theta(E S C) \equiv \text { true }=s(n)>m, \text { true }=m>\bar{z}, m * m=m \rightarrow n * n=n, n>m=\text { true } .
$$

The above CS rule complements the inductive congruence closure rule (ICC) presented later in at least two ways. First, it makes it possible to use those induction hypotheses not usable as rewrite rules, namely, those in the set $H_{n e}$, for clause simplification purposes. In a sense, the CS rule manages to use a clause $\Gamma \rightarrow \Delta$ in $H_{n e}$ "as if it were a rewrite rule," since we can think of such a clause -in a way entirely similar as how clauses $\gamma \rightarrow \Delta^{\prime}$ in $H_{\mathrm{v}, e}^{=}$were oriented as rewrite rules $\Upsilon \rightarrow\left(\Delta^{\prime} \rightarrow \top\right)$ — as a "conditional rewrite rule" of the form $\Gamma \rightarrow(\Delta \rightarrow \top)$ that the CS rule "applies" to the head of a conjecture when part of the conjecture's head matches the lefthand side $\Delta$ and the condition $\Gamma$ is "satisfied" by part of the conjecture's premise matching it. Second, since the CS rule is computationally less expensive that ICC and all hypotheses in $H$ can be used for subsumption, the CSrule also complements the heavier artillery of ICC, because it may blow away some conjectures without having to bring in ICC itself. In practice, therefore, CS should be tried before ICC to pick any low-hanging fruit that may be around.

Equation Rewriting (Left and Right) (ERL and ERR).

$$
(\mathbf{E R L}) \frac{[\bar{X}, \mathcal{E}, H] \Vdash\left(u^{\prime}=v^{\prime}\right) \theta, \Gamma \rightarrow \Lambda \quad[\varnothing, \mathcal{E}, \varnothing] \Vdash u=v \Leftrightarrow u^{\prime}=v^{\prime}}{[\bar{X}, \mathcal{E}, H] \Vdash w=w^{\prime}, \Gamma \rightarrow \Lambda}
$$

$$
(\mathbf{E R R}) \frac{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda \wedge\left(\left(u^{\prime}=v^{\prime}\right) \theta, \Delta\right) \quad[\varnothing, \mathcal{E}, \varnothing] \Vdash u=v \Leftrightarrow u^{\prime}=v^{\prime}}{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda \wedge\left(w=w^{\prime}, \Delta\right)}
$$

where there is a substitution $\theta$ such that $\left(w=w^{\prime}\right)=_{B^{=}}(u=v) \theta, \operatorname{vars}\left(u^{\prime}=v^{\prime}\right) \subseteq \operatorname{vars}(u=$ $v),(u=v)>\left(u^{\prime}=v^{\prime}\right)$, and $[\varnothing, \mathcal{E}, \varnothing] \Vdash u=v \Leftrightarrow u^{\prime}=v^{\prime}$ abbreviates $t w o$ different goals: $[\varnothing, \mathcal{E}, \varnothing] \Vdash u=v \rightarrow u^{\prime}=v^{\prime}$ and $[\varnothing, \mathcal{E}, \varnothing] \Vdash u^{\prime}=v^{\prime} \rightarrow u=v$. The equivalence $(u=v) \Leftrightarrow\left(u^{\prime}=v^{\prime}\right)$ should be verified ahead of time as a separate proof obligation, so that it can be used automatically to simplify many goals containing any equations $w_{1}=w_{2}$ that are instances of $u=v$ modulo $B^{=}$, without requiring reproving $(u=v) \Leftrightarrow\left(u^{\prime}=v^{\prime}\right)$ each time. This provides a general method to fully automate rules ERL and ERR so that
they are subsumed $\sqrt{26}$ by the EPS simplification rule when the equality predicate theory $\overrightarrow{\mathcal{E}}_{U}^{=}$(and therefore the given inductive theory) has been extended with reductive rules of the form $(u=v) \rightarrow\left(u^{\prime}=v^{\prime}\right)$ proved as lemmas ${ }^{27}$ that is, after we have proved the lemma $(u=v) \Leftrightarrow\left(u^{\prime}=v^{\prime}\right)$. Note that what we are exploiting in the ERL and ERR rules is the fundamental equivalence:

$$
T_{\mathcal{E}}=\varphi \Leftrightarrow \psi \quad \text { iff } \quad T_{\mathcal{E}}=\models=\psi
$$

from Section 2.5, together with the property $(u=v)>\left(u^{\prime}=v^{\prime}\right)$, which allows us to orient the equation $(u=v)=\left(u^{\prime}=v^{\prime}\right)$ between Boolean terms as a reductive rewrite rule $(u=v) \rightarrow\left(u^{\prime}=v^{\prime}\right)$.

For an example of a useful rewrite rule of this kind, one can prove for natural number addition in, say, Peano notation, the equivalence $x+z=y+z \Leftrightarrow x=y$ and then use it as the reductive $\Sigma^{=}$-rewrite rule $x+z=y+z \rightarrow x=y$ to simplify, by means of the ERL and ERR rules, natural arithmetic expressions.

## Inductive Congruence Closure (ICC).

The next simplification rule is the ICC rule. Since this is one of the most complex rules in the inference system, to help the reader I first explain a simpler congruence closure rule, which has not been made part of the inference system because ICC is a more powerful extension of it. As shown below, ICC is more powerful because it can draw useful inductive consequences (thus the "I" in ICC) that cannot be drawn with congruence closure alone.

Furthermore, even though congruence closure and ICC can be viewed as "modus ponens" steps internal to the given goal $\Gamma \rightarrow \Lambda$, where we assume a convergent equivalent version of the ground condition $\bar{\Gamma}$ to try to prove the ground conclusion $\bar{\Lambda}$ true, we shall see that, even when $\bar{\Lambda}$ cannot be proved true, ICC can still simplify $\Gamma \rightarrow \Lambda$ to $\top$ by showing $\Gamma$ unsatisfiable.

Example 5. Assume a specification $\mathcal{E}$ of the natural numbers in Peano notation with the usual definition of + and with predicates even and odd defined by equations even $(0)=$ $\operatorname{true}, \operatorname{even}(s(0))=\operatorname{false}, \operatorname{even}(s(s(x)))=\operatorname{even}(x), \operatorname{odd}(0)=$ false, and $\operatorname{odd}(s(x))=$ even $(x)$. Now consider that, while proving a bigger theorem, we encounter a subgoal of the form:

$$
[\bar{X}, \mathcal{E}, H] \Vdash \text { even }(n+m)=\operatorname{true}, \text { odd }(n+m)=\text { true } \rightarrow \perp
$$

where $H$ contains the already proved lemma even $(x)=\operatorname{true} \rightarrow o d d(x)=$ false, which is an executable hypothesis with the RPO order generated by the symbol order $+>$ odd $>$ even $>$ not $>s>0>$ false $>$ true. I shall use this as a running example to show the difference between congruence closure and ICC.

[^17]First of all, note that the EPS rule will not change the goal in Example 5] since the goal's condition cannot be further simplified by EPS. An attempt to simplify this goal by applying to it a congruence closure rule of the form:

$$
\frac{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma^{\bullet} \rightarrow \Lambda^{\bullet}}{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda}
$$

where, if $Y=\operatorname{vars}(\Gamma \rightarrow \Lambda)$, then $\bar{\Gamma}$, resp. $\bar{\Lambda}$, denotes the ground formula obtained by instantiating each $y \in Y$ in $\Gamma$, resp. in $\Lambda$, by a fresh constant $\bar{y}$ with same sort as $y$; and, assuming that $\mathcal{E}$ has axioms $B=B_{0} \uplus U$ and recalling the definition of the congruence closure transformation $c c_{B_{0}}^{>}$in Section 2.6, $\bar{\Gamma}^{\bullet}$ is defined as the set of ground equations associated to the ground convergent set of rules $c c_{B_{0}}^{>}(\bar{\Gamma})$, and $\Gamma^{\bullet}$ is obtained from $\bar{\Gamma}^{\bullet}$ by mapping back each such $\bar{y}$ to its corresponding $y \in Y$. Likewise, $\Lambda^{\bullet}$ is obtained in the same manner from $\bar{\Lambda}^{\bullet}$, where, by definition, $\bar{\Lambda}^{\bullet} \in \bar{\Lambda}!_{\overrightarrow{\mathcal{E}}_{\overline{\bar{\chi} \Psi_{U}}}^{=} \cup \vec{H}_{e_{U}}^{+} \cup c c_{B_{0}}^{>}(\bar{T})}$. That is, we simplify $\bar{\Lambda}$ with the combined power or EPS and the convergent rules $c c_{B_{0}}^{>}(\bar{\Gamma})$ to get $\bar{\Lambda}^{\bullet}$. Of course, if $\bar{\Lambda}^{\bullet}=\top$, the entire multiclause $\Gamma \rightarrow \Lambda$ is simplified to $\top$. Note, however, that this congruence closure simplification method leaves the goal in Example 5 untouched. This is because: (i) the rules even $(\bar{n}+\bar{m}) \rightarrow$ true, odd $(\bar{n}+\bar{m}) \rightarrow$ true are already ground convergent, and (ii) $\perp$ cannot be simplified.

A further observation about the limitations of the above congruence closure simplification rule is that the rules in $\overrightarrow{\mathcal{E}}_{\bar{X} \cup Y_{U}}^{=} \cup \vec{H}_{e_{U}}^{+} \cup c c_{B_{0}}^{>}(\bar{\Gamma})$ that we are using for simplifying $\bar{\Lambda}$ can preempt each other, thus becoming less effective. For example, the lefthand side $l$ of a ground rule $l \rightarrow r$ in $c c_{B_{0}}^{>}(\bar{\Gamma})$ may be reducible by some rule in $\overrightarrow{\mathcal{E}} \overline{\overline{X \cup Y_{U}}} \cup \vec{H}_{e_{U}}^{+}$and may for this reason fail to be applied to some ground subterm of $\bar{\Lambda}$, simply because such a subterm was already simplified by the same rule in $\overrightarrow{\mathcal{E}}_{\overline{X \cup Y_{U}}}^{=} \cup \vec{H}_{e_{U}}^{+}$, which can also simplify $l$. This suggests defining the formula:

$$
\bar{\Gamma}^{b}=\operatorname{def} \bigwedge_{(l \rightarrow r) \in c c_{B_{0}}^{>}(\bar{T})}(l=r)!\vec{\varepsilon}_{\bar{X} \cup Y_{U}}^{=} \cup \vec{H}_{e_{U}}^{+}
$$

Note that, as shown in Example 3) since we are performing EPS simplification, ( $l=$ $r)!\overrightarrow{\mathcal{E}}_{\bar{\chi}_{\cup \gamma_{U}}} \cup \vec{H}_{e_{U}}^{+}$need not be a single equation: it can be so; but it can also be a disjunction or conjunction of equations, or $\top$ or $\perp$. Therefore, by putting $\bar{\Gamma}^{b}$ in disjunctive normal form, it can be either $\top$, or $\perp$, or a disjunction of conjunctions of the form $\vec{\Gamma}^{b}=\bigvee_{i \in I} \bar{\Gamma}_{i}^{b}$. We can then define $\overrightarrow{\bar{\Gamma}}^{b}=\bigvee_{i \in I} \overrightarrow{\bar{\Gamma}}_{i}^{b}$, where $\vec{\Gamma}_{i}^{b}=$ def $^{\text {orient }} \gg\left(\bar{\Gamma}_{i}^{b}\right)$, where orient $_{\succ}\left(\bar{\Gamma}_{i}^{b}\right)$ denotes the set of ground rewrite rules associated to the ground equations in $\bar{\Gamma}_{i}^{b}$ according to the RPO order $>$. This has several important advantages over the above congruence closure simplification method. First, we may have $\bar{\Gamma}^{b}=\perp$, showing $\Gamma$ unsatisfiable and thus proving the given goal $\Gamma \rightarrow \Lambda$ true. For example, one of the rules in $c c_{B_{0}}^{>}(\bar{\Gamma})$ may be of the form $s(\bar{v}) \rightarrow 0$, with 0 and $s$ the natural zero and successor symbols, so that the ground equation $s(\bar{v})=0$ will be EPS-simplified to $\perp$, making $\bar{\Gamma}^{b}=\perp$. Second, a rule in $c c_{B_{0}}^{>}(\bar{\Gamma})$ may become much more widely applicable when transformed into a
rule in some $\overline{\bar{\Gamma}}_{i}^{\mathrm{b}}$. For example, a ground rule of the form $s(\bar{u}) \rightarrow s(\bar{v})$ in $c c_{B_{0}}^{>}(\bar{\Gamma})$ may become in some $\vec{\Gamma}_{i}^{b}$ either a rule $\bar{u}^{\prime} \rightarrow \bar{v}^{\prime}$, or $\bar{v}^{\prime} \rightarrow \bar{u}^{\prime}$, depending on the RPO-ordering of the simplified forms $\bar{u}^{\prime}$ and $\bar{v}^{\prime}$ of $\bar{u}$ and $\bar{v}$, making such a rule much more widely applicable. However, even with all these improvements, for our goal in Example 5 we still get $\vec{\Gamma}^{b}=\{\operatorname{even}(\bar{n}+\bar{m}) \rightarrow$ true, odd $(\bar{n}+\bar{m}) \rightarrow$ true $\}$ because: (i) EPS simplification leaves these rules untouched, and (ii) the inductive lemma even $(x)=$ true $\rightarrow$ odd $(x)=$ false cannot be applied to simplify $\operatorname{odd}(\bar{n}+\bar{m})$ to false, since the needed assumption even $(x)=\operatorname{true}$ cannot be proved with the rules in $\overrightarrow{\mathcal{E}}=\overline{X \cup Y}_{U} \cup \vec{H}_{e_{U}}^{+}$. So, even this more powerful form of congruence closure still leaves the goal in Example 5 untouched.

This suggests one more turning of the screw, finally bringing us to our desired ICC rule, namely, to inter-reduce the rules in $\overrightarrow{\bar{T}}^{b}$ by defining:

$$
\left.\bar{\Gamma}^{\sharp}=\operatorname{def} \bigwedge_{(l \rightarrow r) \in c c c_{B_{0}}^{>}}(\bar{\Gamma}) \mathrm{l}=r\right)!_{\overrightarrow{\mathcal{C}_{\bar{X}}^{=}}{ }_{\overline{Y_{U}}} \cup \vec{H}_{e_{U}}^{+} \cup c c_{B_{0}}^{>}(\bar{\Gamma}) \backslash\{l \rightarrow r\}}
$$

and then defining $\bar{\Gamma}^{\sharp}=\bigvee_{i \in I} \bar{\Gamma}_{i}^{\sharp}$ and $\vec{\Gamma}^{\sharp}=\bigvee_{i \in I} \vec{\Gamma}_{i}^{\sharp}$ in the same way as we defined $\bar{\Gamma}^{b}$, $\overrightarrow{\bar{\Gamma}}^{b}$, and the $\bar{\Gamma}_{i}^{b}$ and $\vec{\Gamma}_{i}^{b}$. This is indeed a powerful enough method to prove our goal in Example [5] since now we can inter-reduce the equation $\operatorname{odd}(\bar{n}+\bar{m})=$ true with the rules $\overrightarrow{\mathcal{E}}={\bar{X} \cup Y_{U}}^{=} \vec{H}_{e_{U}}^{+} \cup\{\operatorname{even}(\bar{n}+\bar{m}) \rightarrow$ true $\}$, which allow the inductive lemma even $(x)=\operatorname{true} \rightarrow$ $\operatorname{odd}(x)=$ false to be appied to simplify the above equation to false $=$ true, which is then EPS-simplified to $\perp$.

Note that, since we have the Boolean equivalence $(A \vee B) \Rightarrow C \equiv(A \Rightarrow C) \wedge(B \Rightarrow C)$, when performing ICC simplification of $\bar{\Lambda}$ by means of $\overrightarrow{\bar{\Gamma}}^{\sharp}$, we in general may get not a single subgoal but several of them, each corresponding to a different set of ground rules $\overrightarrow{\bar{\Gamma}}_{i}^{\sharp}$. By bluring the distinction between the $\wedge^{\wedge} \wedge^{\ldots}$ and the ${ }_{\_}, \ldots$ notation for conjunction, we then get our desired ICC inference rule:

$$
(\mathbf{I C C}) \frac{\left\{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma_{i}^{\sharp} \rightarrow \Lambda_{i}^{\sharp}\right\}_{i \in I}}{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda}
$$

where: (i) by definition, $\bar{\Lambda}_{i}^{\sharp} \in \bar{\Lambda}!{\underset{\vec{\varepsilon}}{\bar{X} \cup Y_{U}}}^{=} \cup \vec{H}_{e_{U}}^{+} \cup \overrightarrow{\bar{T}}_{i}^{\sharp}$, and we always pick $\bar{\Lambda}_{i}^{\sharp}=\top$ if $\top \in$ $\bar{\Lambda}!_{\vec{\varepsilon}_{\overline{X U Y}_{U}}^{=} \cup \vec{H}_{e_{U}}^{+} \cup \bar{\Gamma}_{i}^{\sharp}}$; (ii) $\Gamma_{i}^{\sharp} \rightarrow \Lambda_{i}^{\sharp}$ is obtained from $\bar{\Gamma}_{i}^{\sharp} \rightarrow \bar{\Lambda}_{i}^{\sharp}$ by converting back the Skolem constants associated to the variables of $\Gamma \rightarrow \Lambda$ into those same variables, and (iii) the case $\bar{\Gamma}^{\sharp}=\perp$ is the case when there are no conjunctions in the disjunctive normal form $\bar{\Gamma}^{\sharp}$, i.e., $I=\varnothing$, so that, by convention, the notation $\left\{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma_{i}^{\sharp} \rightarrow \Lambda_{i}^{\sharp}\right\}_{i \in \varnothing}$ then denotes $T$, because, since $\Gamma$ has been shown inductively unsatisfiable, the goal is proved. Note that when $\bar{\Gamma}^{\sharp}=\top,|I|=1$, and what we get is the subgoal $[\bar{X}, \mathcal{E}, H] \Vdash \Lambda^{\prime}$, with $\overline{\Lambda^{\prime}} \in \bar{\Lambda}!_{\overrightarrow{\mathcal{E}}_{\bar{X} \cup Y_{U}}^{=}} \cup \vec{H}_{e U}^{+}$.
Note the close connection between the ICC and EPS rules: when the premise $\Gamma$ of the goal $\Gamma \rightarrow \Lambda$ is $\top$, then ICC coincides with EPS. This means that it is useless to apply ICC
when $\Gamma$ is $T$. But since EPS is a simpler and computationally less expensive rule than ICC, when $\Gamma$ is a non-trivial premise it is a good strategy to always apply EPS before applying ICC.

Example 6. Consider the EPS-simplified goal

$$
[\varnothing, \mathcal{N P}, \varnothing] \Vdash x * x=s(y), y=0 \rightarrow x+(x * x)=s(x+y) \wedge x * x=x
$$

from Example 3 We want to further simplify it using ICC. Suppose that, after adding new constants $\bar{x}$ and $\bar{y}$ to the signature of $\mathcal{N P}$, we linearly order its symbols in the chain:

$$
(-)^{(-)}>*>+>\bar{x}>\bar{y}>s>0 .
$$

Then, the congruence closure of the ground equations $\bar{\Gamma}=\{\bar{x} * \bar{x}=s(\bar{y}), \bar{y}=0\}$ using the associated RPO order is the set of rules $\{\bar{x} * \bar{x} \rightarrow s(0), \bar{y} \rightarrow 0\}$, which, since it cannot be further simplified by the rules in $\overrightarrow{\mathcal{N P}}{ }^{=}$, there are no induction hypotheses, and is already inter-reduced, is just $\vec{\Gamma}^{\sharp}$. In this case, $\bar{\Lambda}=\bar{x}+(\bar{x} * \bar{x})=s(\bar{x}+\bar{y}) \wedge \bar{x} * \bar{x}=\bar{x}$, which is simplified by $\overrightarrow{\mathcal{N P}}=\overrightarrow{\bar{\Gamma}}^{\sharp}$ (where $\overrightarrow{\mathcal{N P}}=$ includes the rule $x=x \rightarrow \top$ ) to $s(0)=\bar{x}$. Therefore, ICC has simplified our goal to the considerably simpler goal,

$$
[\varnothing, \mathcal{N P}, \varnothing] \Vdash x * x=s(0), y=0 \rightarrow s(0)=x
$$

## Variant Satisfiability (VARSAT).

$$
\frac{\top}{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda}
$$

if $\Gamma \rightarrow \Lambda$ is an $\mathcal{E}_{1}$-formula and $\neg\left(\Gamma^{\circ} \rightarrow \Lambda^{\circ}\right)$ is unsatisfiable in $T_{\mathcal{E}_{1}}$, where $\Gamma^{\circ} \rightarrow \Lambda^{\circ}$ is obtained from $\Gamma \rightarrow \Lambda$ by replacing constants in $\bar{X}$ by corresponding variables in $X$. This rule can be automated because being a $\mathcal{E}_{1}$-formula is a syntactic condition. Furthermore, since $\mathcal{E}_{1}$ is FVP and sufficiently complete on free constructors modulo $A \vee C$ axioms, satisfiability in $T_{\mathcal{E}_{1}}$ (and therefore in $T_{\mathcal{E}}$, since $\left.T_{\mathcal{E}}\right|_{\Sigma_{1}} \cong T_{\mathcal{E}_{1}}$ ) is decidable [54].

One could politely ask: why VARSAT and not a more general rule allowing any combination of decision procedures? Why not indeed? The purely pragmatic reason why VARSAT only supports variant satisfiability is that it is already there. It has been used effectively together with the other simplification rules in discharging many verification conditions in a large proof effort such as the proof of the IBOS browser security discussed in [49]. Variant satisfiability makes SMT solving user-extensible to an infinite class of user-definable data types [54], and therefore complements the domain-specific decision procedures supported by current SMT solvers. One of course wants both: the efficiency of domain-specific procedures and VARSAT's user-definable extensibility. Therefore, VARSAT should in the future be generalized to a VARSAT + SMT simplification rule that combines domain-specific procedures and variant satisfiability.

### 4.2 Inductive Rules

## Generator Set Induction (GSI).

The generator set induction rule is a substantial generalization of structural induction on constructors. In both structural induction and its GSI generalization one inducts on a variable $z$ in the conjecture.

$$
\frac{\left\{\left[\bar{X}_{\uplus} \bar{Y}_{i}^{\bullet}, \mathcal{E},\left(H \uplus H_{i}\right)_{\text {simp }}\right] \Vdash\left(\Gamma \rightarrow \bigwedge_{j \in J} \Delta_{j}\right)\left\{z \mapsto \bar{u}_{i}^{\bullet}\right\}\right\}_{1 \leqslant i \leqslant n}}{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \bigwedge_{j \in J} \Delta_{j}}
$$

where $z \in \operatorname{vars}\left(\Gamma \rightarrow \bigwedge_{j \in J} \Delta_{j}\right)$ has sort $s,\left\{u_{1} \cdots u_{n}\right\}$ is a $B_{0}$-generator set for $s$, with $B_{0}$ the axioms of the transformed ground convergent theory $\overrightarrow{\mathcal{E}}_{U}$, and with $Y_{i}$ fresh variables $Y_{i}=\operatorname{vars}\left(u_{i}\right)$ for $1 \leqslant i \leqslant n$. The set of induction hypotheses $H_{i}$ is then, by definition, the set

$$
H_{i}=\left\{\left(\left(\Gamma \rightarrow \Delta_{j}\right)\{z \rightarrow \bar{v}\}\right)!_{\vec{\varepsilon}_{\bar{X}}=\overline{\bar{T}}_{i U}} \mid v \in P S T_{B_{0}, \leqslant s}\left(u_{i}\right) \wedge j \in J\right\}
$$

where, by definition, $\operatorname{PST}_{B_{0}, \leqslant s}\left(u_{i}\right)=\left\{v \in P S T_{B_{0}}\left(u_{i}\right) \mid l s(v) \leqslant s\right\}$ (recall the notion of proper $B_{0}$-subterm in Definition 2, and Remark 1 there), and $\bar{v}$ denotes the instantiation of $v$ by the substitution $\{y \mapsto \bar{y}\}_{y \in Y_{i}}$. By notational convention: (1) when $P S T_{B_{0}, \leqslant s}\left(u_{i}\right) \neq \varnothing$ and the set of induction hypotheses $H_{i}$ for constructor term $u_{i}$ are nontrivial, i.e., at least for some $j \in J$ we have $\left(\left(\Gamma \rightarrow \Delta_{j}\right)\{z \rightarrow \bar{v}\}\right)!{\stackrel{\rightharpoonup}{\bar{X}_{\boxplus}} \overline{\bar{Y}}_{i U}} \neq \top$ (trivial induction hypotheses are always omitted), then $\bar{Y}_{i}^{\bullet} \equiv \bar{Y}_{i}$ are fresh constants $\bar{y}$, with the same sorts, for each $y \in Y_{i}$, and $\bar{u}_{i}^{\bullet} \equiv \bar{u}_{i}$ denotes the instantiation of $u_{i}$ by the substitution $\{y \mapsto \bar{y}\}_{y \in Y_{i}} ;$ (2) otherwise, i.e., when either $Y_{i}=\varnothing$, or all the simplified induction hypotheses $H_{i}$ are trivial, then, $\bar{Y}_{i}^{\bullet} \equiv \varnothing$, and $\bar{u}_{i}^{\bullet} \equiv u_{i}$. That is, in case (2) the inductive subgoal for constructor term $u_{i}$ has no (nontrivial) induction hypotheses, and then we neither introduce new constants $\bar{Y}_{i}$ nor instantiate $u_{i}$ with them. Note, finally, that the new sets of hypotheses $H \uplus H_{i}$ are simplified for each $1 \leqslant i \leqslant n$ in the way described in Section 3.2

Let me illustrate the GSI rule with two examples. The first example should be familiar to many readers, but may still be helpful to illustrate the notation and use of GSI. The second shows both the versatility and the proving power added by GSI to standard structural induction.

Example 7. Suppose we are building lists of natural numbers with two constructors: nil, and a "cons" operator.$_{-}$: Nat List $\rightarrow$ List, and we want to prove the associativity of the list append operator_@_:List List $\rightarrow$ List, defined with the usual recursive equations $n i l @ L=L$ and $(n \cdot L) @ Q=n \cdot(L @ Q)$, where $n, m$ have sort $N a t$, and $L, P, Q, R$ have sort List. Let us call this theory $\mathcal{L}_{\text {cons }}$. That is, we want to prove the goal:
$\left[\varnothing, \mathcal{L}_{\text {cons }}, \varnothing\right] \Vdash(L @ P) @ Q=L @(P @ Q)$.
We can do so by applying the GSI rule on variable $L$ with generator set $\{n i l, m \cdot R\}$, i.e., by structural list induction. We get two goals. Goal (1) for nil easily simplifies to T. Goal (2) for $m \cdot R$ also easily simplifies to $T$. The point, however, is to illustrate how this second subgoal is generated according to rule GSI and is simplified to $\top$ by the EPS simplification rule. $Y_{2}=\{m, R\}$, and $P S T_{B_{0}, \leqslant L i s t}(m \cdot R)=\{R\}$. Therefore, we get the subgoal:
$\left[\{\bar{m}, \bar{R}\}, \mathcal{L}_{\text {cons }},\{(\bar{R} @ P) @ Q=\bar{R} @(P @ Q)\}\right] \Vdash(\bar{m} \cdot \bar{R} @ P) @ Q=\bar{m} \cdot \bar{R} @(P @ Q)$. and $H_{2}$ is the induction hypothesis $(\bar{R} @ P) @ Q=\bar{R} @(P @ Q)$. Since in the standard $\underline{\mathrm{RPO}}$ order we have $(\bar{R} @ P) @ Q>\bar{R} @(P @ Q), H_{2}$ can be used as the rewrite rule $(\bar{R} @ P) @ Q \rightarrow$ $\bar{R} @(P @ Q)$. The EPS rule can simplify the subgoal $(\bar{m} \cdot \bar{R} @ P) @ Q=\bar{m} \cdot \bar{R} @(P @ Q)$ to $\top$ because, using the second recursive equation, it simplifies to $\bar{m} \cdot(\bar{R} @ P) @ Q=$ $\bar{m} \cdot \bar{R} @(P @ Q)$, which using the induction hypothesis is rewritten to $\bar{m} \cdot \bar{R} @(P @ Q)=$
$\bar{m} \cdot \bar{R} @(P @ Q)$, which using the equationally-defined equality predicate rules in $\mathcal{L}_{\text {cons }}^{=}$is finally reduced to $T$.
Example 8. This example similar to Example 2 in Section 2.10 on proving commutativity of natural number addition for the Peano naturals, i.e., the goal is $x+y=y+x$. But here we prove commutativity for the "twice as fast" definition of addition: $n+0=$ $n, n+s(0)=s(n), n+s(s(m))=s(s(n+m))$. We induct on $x$ applying the GSI rule with generator set $\{0, s(0), s(s(k))\}$. Subgoal (1), the subgoal for 0 , is $0+y=y+0$, which simplifies to $0+y=y$ and cannot be further simplified. We apply again the GSI rule inducting on $y$. The sub-subgoals for 0 and $s(0)$ are trivially simplified. The simplified sub-subgoal for $s(s(\bar{k}))$ is $s(s(0+\bar{k}))=s(s(\bar{k}))$. Since $P S T_{B_{0}, \leqslant N a t}(s(s(k)))=\{k, s(k)\}$, we get the induction hypotheses: $0+\bar{k}=\bar{k}$ and $0+s(\bar{k})=s(\bar{k})$, which are both reductive. The EPS rule then first simplifies this sub-subgoal to $s(s(\bar{k}))=s(s(\bar{k}))$ using the first hypothesis, which is then simplified to $T$ by the equality predicate rules.

The simplified versions of the other two subgoals of the original goal are: (2) $s(0)+y=$ $s(y)$, and (3) $s\left(s\left(\overline{k^{\prime}}\right)\right)+y=s\left(s\left(y+\overline{k^{\prime}}\right)\right)$. The reader can check that, for both (2) and (3), a further induction on $y$ followed by EPS simplification also discharges them. It is also interesting to see that, as already happened in Example 2 it is only by using the "background-theory-aware" semantics of ordered rewriting that the entire commutative law can be proved without any need for extra lemmas.
This example illustrates two main points. First, the versatility of the GSI rule in being able to use the "right" generator set for each function, based on its recursive equations. This often substantially helps the formula simplification process. The second point is the added power of generating induction hypotheses, not just for the variables of a term $u_{i}$ in the generator set whose sort is smaller than or equal to the induction variable's sort $s$, but also for all other proper subterms of $u_{i}$ whose least sort is smaller than or equal to $s$. Here this is illustrated by the fact that $P S T_{B_{0}, \leqslant N a t}(s(s(k)))=\{k, s(k)\}$, so that two induction hypotheses are generated for $s(s(k))$. In general, of course, this provides a stronger induction principle than just generating induction hypotheses for the variables of $u_{i}$. This increases the chances of success in simplifying conjectures by applying the additional induction hypotheses to subcalls of the function (or functions) whose recursive equations suggested the choice of the generator set. This is analogous to the way in which strong induction on the natural numbers is stronger than standard induction.

Remark 2. The GSI rule could be further generalized by allowing the notion of $B_{0^{-}}$ generator set for a sort $s$ to be, not just a set $\left\{u_{1} \cdots u_{n}\right\}$, but a set of $\Sigma$-constrained terms $\left\{u_{1}\left|\varphi_{1} \cdots u_{n}\right| \varphi_{n}\right\}$ such that $T_{\Omega / B_{0}, s}=\bigcup_{1 \leqslant i \leqslant n} \llbracket u_{i} \mid \varphi_{i} \rrbracket$, where, by definition, $\llbracket u \mid \varphi \rrbracket=\{[v] \in$ $T_{\Omega / B_{0}} \mid \exists \rho \in\left[X \rightarrow T_{\Omega}\right]$ s.t. $\left.[v]=[u \rho] \wedge \mathcal{E} \vdash \varphi \rho\right\}$, where $X=\operatorname{vars}(u)$ and $\varphi$ is a QF $\Sigma$-formula with $\operatorname{vars}(\varphi) \subseteq \operatorname{vars}(u)$. Why could this be useful? Because it would allow what one might call "bespoke generator sets," tailor made for a specific function or set of functions $f$ involving conditional equations in their definition. The reason why the GSI rule was not specified in this more general form is that, the "bespoke" nature of such a generalization is implicitly provided by another inference rule, namely, the NI rule to be presented next. However, if future experimentation suggests that it would be useful to have this more general form of the GSI rule explicitly available, it could be added to the present inference system as a natural generalization.

## Narrowing Induction (NI).

$$
\frac{\left\{\left[\bar{X}_{\uplus} \bar{Y}_{i, j}^{*}, \mathcal{E},\left(H \uplus\left(H_{i, j}\right)!_{\overline{\mathcal{E}}_{\overline{\bar{x}} \overline{\bar{T}}_{i, j}}}\right)_{\operatorname{simp}}\right] \Vdash\left(\Gamma_{i,},\left(\Gamma \rightarrow \bigwedge_{l \in L} \Delta_{l}\right)\left[r_{i}\right]_{p}\right) \bar{\alpha}_{i, j}^{\bullet} j_{i \in I_{0}}^{j \in J_{i}}\right.}{[\bar{X}, \mathcal{E}, H] \Vdash\left(\Gamma \rightarrow \bigwedge_{l \in L} \Delta_{l}\right)[f(\vec{v})]_{p}}
$$

where:

1. $f(\vec{v})$ does not contain any constants in $\bar{X}$. We call $f(\vec{v})$ the focus narrowex of goal $\Gamma \rightarrow \bigwedge_{l \in L} \Delta_{l}$ at position $p$.
2. $f$ is a non-constructor symbol in $\Sigma \backslash \Omega$, the terms $\vec{v}$ are $\Omega$-terms, and $f$ is defined in the transformed ground convergent theory $\overrightarrow{\mathcal{E}}_{U}$ by a family of (possibly conditional) rewrite rules (with constructor argument subcalls), of the form: $\left\{[i]: f\left(\overrightarrow{u_{i}}\right) \rightarrow\right.$ $r_{i}$ if $\left.\Gamma_{i}\right\}_{i \in I}$ such that: (i) are renamed with fresh variables disjoint from those in $X$ and in $\Gamma \rightarrow \bigwedge_{l \in L} \Delta_{l}$; (ii) as assumed throughout, for each $i \in I, \operatorname{vars}\left(f\left(\vec{u}_{i}\right)\right) \supseteq$ $\operatorname{vars}\left(r_{i}\right) \cup \operatorname{vars}\left(\Gamma_{i}\right)$ and the rules are sufficiently complete, i.e., can rewrite modulo the axioms $B_{0}$ of $\overrightarrow{\mathcal{E}}_{U}$ any $\Sigma$-ground term of the form $f(\vec{w})$, with the $\vec{w}$ ground $\Omega$-terms; and (iii) are the transformed rules by the $\overrightarrow{\mathcal{E}} \mapsto \overrightarrow{\mathcal{E}}_{U}$ transformation of corresponding rules defining $f$ in $\overrightarrow{\mathcal{E}}$ and are such that, as explained in Footnote 9 never lose their lefthandside's top symbol $f$ in the $\overrightarrow{\mathcal{E}} \mapsto \overrightarrow{\mathcal{E}}_{U}$ transformation due to a $U$-collapse.
3. For each $i \in I$, $\operatorname{Unif}_{B_{0}}\left(f(\vec{v})=f\left(\overrightarrow{u_{i}}\right)\right)$ is a family of $B_{0}$-unifiers Unif $B_{B_{0}}\left(f(\vec{v})=f\left(\overrightarrow{u_{i}}\right)\right)=$ $\left\{\alpha_{i, j}\right\}_{j \in J_{i}}$, with $I_{0}=\left\{i \in I \mid \operatorname{Unif}_{B_{0}}\left(f(\vec{v})=f\left(\overrightarrow{u_{i}}\right)\right) \neq \varnothing\right\}$, and with $\operatorname{dom}\left(\alpha_{i, j}\right)=$ $\operatorname{vars}(f(\vec{v})) \uplus \operatorname{vars}\left(f\left(\overrightarrow{u_{i}}\right)\right), Y_{i, j}=\operatorname{ran}\left(\alpha_{i, j}\right)$ fresh variables not appearing anywhere, $\bar{Y}_{i, j}$ denotes the set of fresh constants $\bar{y}$ of same sort for each variable $y \in Y_{i, j}$, and $\bar{\alpha}_{i, j}$ denotes the composed substitution $\bar{\alpha}_{i, j}=\alpha_{i, j}\{y \mapsto \bar{y}\}_{y \in Y_{i, j}}$.
4. $H_{i, j}$ is defined by cases, depending on where position $p$ occurs in $\Gamma \rightarrow \bigwedge_{l \in L} \Delta_{l}$. Case (1): If $p$ occurs in $\Gamma$, then $H_{i, j}=\left\{\left(\Gamma \rightarrow \Delta_{l}\right) \bar{\gamma} \mid l \in L \wedge f(\vec{w}) \in \operatorname{SSC}([i]) \wedge f(\vec{w}) \alpha_{i, j}={ }_{B_{0}}\right.$ $f(\vec{v}) \gamma\}$. Case (2): If $p$ occurs in some $\Delta_{k}$ in $\bigwedge_{l \in L} \Delta_{l}$, then $H_{i, j}=\left\{\left(\Gamma \rightarrow \Delta_{k}\right) \bar{\gamma} \mid f(\vec{w}) \in\right.$ $\left.\operatorname{SSC}([i]) \wedge f(\vec{w}) \alpha_{i, j}={ }_{B_{0}} f(\vec{v}) \gamma\right\}$. In both cases $\bar{\gamma}$ is, by definition, the composed substitution $\bar{\gamma}=\gamma\{y \mapsto \bar{y}\}_{y \in Y_{i, j}}$.
5. By notational convention, (1) when the simplified induction hypotheses $\left(H_{i, j}\right)!_{\overrightarrow{\mathcal{E}}}^{\overline{\bar{X}}_{\uplus \bar{Y}_{i, j}}}{ }^{-}$ are nontrivial (i.e., non-empty and at least one does not simplify to T ), then $\bar{Y}_{i, j}^{\bullet}=\bar{Y}_{i, j}$, and $\bar{\alpha}_{i, j}^{\bullet}=\bar{\alpha}_{i, j}$; (2) otherwise, i.e., when the simplified induction hypotheses of the $i, j$-th inductive subgoal are trivial, then, $Y_{i, j}^{\bullet}=\varnothing$, and $\bar{\alpha}_{i, j}^{\bullet}=\alpha_{i, j}$.
Note that, by the way the induction hypotheses $H_{i, j}$ are defined in (4) above, if $\bigwedge_{l \in L} \Delta_{l}$ contains more than one disjunction $\Delta_{l}$, i.e., if the goal is properly a multiclause and not just a clause, there are definite advantages in choosing a positon $p$ for the focus narrowex in the goal's premise $\Gamma$, since this will have a "gunshot" effect of producing as many induction hypotheses as conjuncts $\Delta_{l}$ in $\bigwedge_{l \in L} \Delta_{l}$, which may simultaneously help in proving all such conjuncts (see Section 5 for an example).
The above, somewhat long, list of technical details specifying the NI rule is of course essential for its precise definition, proof of soundness, and correct implementation. But it may obscure its intuitive meaning, which can be clarified and illustrated by means of an example.

Example 9. Consider a signature of constructors $\Omega$ for non-empty lists of elements (the constructors for such elements are irrelevant), with sorts Elt and List, a subsort inclusion Elt $<$ List, an associative (A) list concatenation operator _ . $:$ List List $\rightarrow$ List,
and a convergent and sufficiently complete list reverse function rev: List $\rightarrow$ List, defined by the equations oriented as rules, [1]: $\operatorname{rev}(x) \rightarrow x$ (which has no subcalls), and [2]: $\operatorname{rev}(x \cdot L) \rightarrow \operatorname{rev}(L) \cdot x$, with $S S C([2])=\{\operatorname{rev}(L)\}$, where $x, x^{\prime}, y, y^{\prime}$ have sort Elt, and $L, P, Q$ have sort List. Note that in this example $U=\varnothing$, and therefore $\overrightarrow{\mathcal{E}}=\overrightarrow{\mathcal{E}}_{U}$.

We would like to prove the inductive lemma:

$$
\operatorname{rev}(Q \cdot y)=y \cdot \operatorname{rev}(Q)
$$

We can do so by applying the NI rule to the conjecture's lefthand side as our focus narrowex, i.e., by trying to narrow ${ }^{28}$ it with the two rules defining rev. Rule [1] has no $A$-unifiers. Rule [2] has two most general $A$-unifiers, namely, $\alpha_{2,1}=\left\{x \mapsto x^{\prime}, Q \mapsto x^{\prime}, y \mapsto\right.$ $\left.y^{\prime}, L \mapsto y^{\prime}\right\}$, with $Y_{2,1}=\left\{x^{\prime}, y^{\prime}\right\}$, and $\alpha_{2,2}=\left\{x \mapsto x^{\prime}, y \mapsto y^{\prime}, L \mapsto P \cdot y^{\prime}, Q \mapsto x^{\prime} \cdot P\right\}$, with $Y_{2,1}=\left\{x^{\prime}, y^{\prime}, P\right\}$.
With $\alpha_{2,1}$, since for the subcall $\operatorname{rev}(L)$ we get the instance $\operatorname{rev}(L) \alpha_{2,1}=\operatorname{rev}\left(y^{\prime}\right)$, which does not match the focus narrowex $\operatorname{rev}(Q \cdot y)$ as an instance modulo $A, H_{2,1}=\varnothing$, and we just get the subgoal $\operatorname{rev}\left(y^{\prime}\right) \cdot x^{\prime}=y^{\prime} \cdot \operatorname{rev}\left(x^{\prime}\right)$, which simplifies to $\top$.
With $\alpha_{2,2}$, the subcall $\operatorname{rev}(L)$ yields the instance $\operatorname{rev}(L) \alpha_{2,2}=\operatorname{rev}\left(P \cdot y^{\prime}\right)$, which does match the focus narrowex $\operatorname{rev}(Q \cdot y)$ as an instance modulo $A$ with substitution $\gamma=\{Q \mapsto$ $\left.P, y \mapsto y^{\prime}\right\}$. Therefore, $\bar{Y}_{2,2}^{\bullet}=\bar{Y}_{2,2}=\left\{\overline{x^{\prime}}, \overline{y^{\prime}}, \bar{P}\right\}, \bar{\alpha}_{2,2}^{\bullet}=\hat{\bar{\alpha}}_{2,2}$, and $\bar{\gamma}=\left\{Q \mapsto \bar{P}, y \mapsto \overline{y^{\prime}}\right\}$. And we get $H_{2,2}=\left\{\operatorname{rev}\left(\bar{P} \cdot \overline{y^{\prime}}\right)=\overline{y^{\prime}} \cdot \operatorname{rev}(\bar{P})\right\}$ (which is already simplified), and the subgoal $\operatorname{rev}\left(\bar{P} \cdot \overline{y^{\prime}}\right) \cdot \overline{x^{\prime}}=\overline{y^{\prime}} \cdot \operatorname{rev}\left(\overline{x^{\prime}} \cdot \bar{P}\right)$, which simplifies to $\operatorname{rev}\left(\bar{P} \cdot \overline{y^{\prime}}\right) \cdot \overline{x^{\prime}}=\overline{y^{\prime}} \cdot \operatorname{rev}(\bar{P}) \cdot \overline{x^{\prime}}$, and can, using $H_{2,2}$, be further simplified to $\top$ by means of the EPS simplification rule, thus finishing the proof of the lemma by a single application of NI followed by EPS simplification.

Remark 3. The NI rule can be further generalized to take into account the possibility that a defined binary function symbol $f$ may enjoy axioms such as associativity or associativity-commutativity. For example, we might have an $A C$ defined function symbol _*_ for multiplication of natural numbers. The issue this raises is that we may wish to narrow on a focus narrowex that is not syntactically present in the given multiclause, but is present modulo the given axioms. For example, the multiclause may contain the subexpression $(x * s(x)) * y$ and we may wish to narrow on $x * y$, which is not a proper subterm of it, but is a proper subterm modulo $A C$ (see Section 2.9). The generalization of rule NI allowing us to do this is straightforward. We replace the conclusion part of the inference rule by the more general conclusion:

$$
[\bar{X}, \mathcal{E}, H] \Vdash \Gamma^{\prime} \rightarrow \bigwedge_{l \in L} \Delta_{l}^{\prime}
$$

adding to the side conditions (1)-(6) for the NI rule, just as originally stated, the extra side condition (0):

$$
\left(\Gamma^{\prime} \rightarrow \bigwedge_{l \in L} \Delta_{l}^{\prime}\right)=_{B}\left(\Gamma \rightarrow \bigwedge_{l \in L} \Delta_{l}\right)[f(\vec{v})]_{p}
$$

and keeping the NI rule's premises the same. In what follows, I will assume without further ado that the NI rule can be applied in this generalized from, which frees it from what might be called the "slavery of syntax."

[^18]
## Existential ( $)_{\text {). }}$

$$
\frac{[\varnothing, \mathcal{E}, \varnothing] \Vdash I(\Gamma \rightarrow \Lambda)}{[\varnothing, \mathcal{E}, \varnothing] \Vdash(\exists \chi)(\Gamma \rightarrow \Lambda)}
$$

where $\chi$ is a Skolem signature, $\Gamma \rightarrow \Lambda$ is a $\Sigma \cup \chi$-multiclause, and $I: \chi \rightarrow \mathcal{E}$ is a theory interpretation (see Section2.11). Note that the $(\exists)$ rule only applies when the inductive theory is $[\varnothing, \mathcal{E}, \varnothing]$, that is, at the beginning of the inductive reasoning process, and that $I$ must be provided by the user as a witness (for example, as a view in Maude [13]). See Section 2.11 for a simple example of an arithmetic formula of the form $(\exists \chi)(\Gamma \rightarrow \Lambda)$ and its associated theory interpretation $I: \chi \rightarrow \mathcal{E}$.

Lemma Enrichment (LE).

$$
\frac{\left[\bar{X}_{0}, \mathcal{E}, H_{0}\right] \Vdash \Gamma^{\prime} \rightarrow \bigwedge_{j \in J} 厶_{j}^{\prime} \quad[\bar{X}, \mathcal{E}, H] \Vdash H_{0} \quad\left[\bar{X}, \mathcal{E},\left(H \uplus\left\{\Gamma^{\prime} \rightarrow \Delta_{j}^{\prime}\right\}_{j \in J}\right)_{\text {simp }}\right] \Vdash \Gamma \rightarrow \Lambda}{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda}
$$

where $\varnothing \subseteq \bar{X}_{0} \subseteq \bar{X}$. Common cases of use include either: (a) $\bar{X}_{0}=H_{0}=\varnothing$, or (b) $\bar{X}_{0}=\bar{X}$ and $H_{0}=H$. The use of this inference rule is illustrated in Section5

## Split (SP).

$$
\left.\frac{\left\{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma_{i} \theta, \Gamma \rightarrow \Lambda\right\}_{i \in I}}{} \quad[\bar{X}, \mathcal{E}, H] \Vdash H_{0} \quad\left[\bar{X}_{0}, \mathcal{E}, H_{0}\right] \Vdash \operatorname{cnf}\left(\bigvee_{i \in I} \Gamma_{i}\right)\right]
$$

where $\varnothing \subseteq \bar{X}_{0} \subseteq \bar{X}, \operatorname{vars}\left(\left(\bigvee_{i \in I} \Gamma_{i}\right) \theta\right) \subseteq \operatorname{vars}(\Gamma \rightarrow \Lambda)$, and $\operatorname{cnf}\left(\bigvee_{i \in I} \Gamma_{i}\right)$ denotes the conjunctive normal form of $\bigvee_{i \in I} \Gamma_{i}$, which is a multiclause of the general form $\Lambda^{\prime}$.
This rule is, on purpose, very general. In many cases we may have either: (a) $\bar{X}_{0}=H_{0}=\varnothing$, or (b) $\bar{X}_{0}=\bar{X}$ and $H_{0}=H$. In either case (a) or (b), two very common special cases are: (i) $\Gamma_{i}=\left(u_{i}=v_{i}\right), i \in I$, and (ii) the even simpler subcase of a disjunction $u=$ true $\vee u=$ false, where $u$ is a term of sort Bool and $\theta$ is the identity substitution.

## Case (CAS).

This rule has two modalities: one for $z$ a variable, and another for $\bar{z}$ a (universal) Skolem constant. For $z$ a variable the rule is:

$$
\frac{\left\{[\bar{X}, \mathcal{E}, H] \Vdash(\Gamma \rightarrow \Lambda)\left\{z \mapsto u_{i}\right\}\right\}_{1 \leqslant i \leqslant n}}{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda}
$$

where $z \in \operatorname{vars}(\Gamma \rightarrow \Lambda)$ has sort $s$ and $\left\{u_{1}, \cdots, u_{n}\right\}$ is a $B_{0}$-generator set for sort $s$ with the $u_{i}$ for $1 \leqslant i \leqslant n$ having fresh variables.

For a fresh constant $\bar{z} \in \bar{X}$ of sort $s$ the rule is:

$$
\frac{\left\{\left[\bar{X} \uplus \bar{Y}_{i}, \mathcal{E},\left(H \uplus\left\{\bar{z}=\bar{u}_{i}\right\}\right)_{\operatorname{simp}}\right] \Vdash(\Gamma \rightarrow \Lambda)\left\{\bar{z} \mapsto \bar{u}_{i}\right\}\right\}_{1 \leqslant i \leqslant n}}{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda}
$$

where $\bar{z}$ occurs in $\Gamma \rightarrow \Lambda, Y_{i}=\operatorname{vars}\left(u_{i}\right), \bar{Y}_{i}$ are the corresponding new fresh constants, and $\bar{u}_{i} \equiv u_{i}\{y \mapsto \bar{y}\}_{y \in Y_{i}}$.
The use of this inference rule is illustrated in Section5

## Variable Abstraction (VA).

$$
\frac{[\bar{X}, \mathcal{E}, H] \Vdash u=v[x]_{p}, z=w, \Gamma \rightarrow \Lambda}{[\bar{X}, \mathcal{E}, H] \Vdash u=v[w]_{p}, \Gamma \rightarrow \Lambda}
$$

where $z$ is a fresh variable whose sort is the least sort of subterm $w$ of $v$ at position $p$. VA is particularly effective when the equation $u=v[z]_{p}$ resulting from the abstraction is a $\Sigma_{1}$-equation (this may require several applications of VA), since then it can be unified away by CVUL. For several examples illustrating the application and usefulness of the VA rule, see Section 5

Equality (EQ).

$$
\frac{[\bar{X}, \mathcal{E}, H] \Vdash(\Gamma \rightarrow \Lambda)[v \theta \gamma]_{p}}{[\bar{X}, \mathcal{E}, H] \Vdash(\Gamma \rightarrow \Lambda)[w]_{p}}
$$

where: (i) $w={ }_{B_{0}} u \theta \gamma$; (ii) $\Gamma^{\prime} \rightarrow u=v$ is a conditional equation in either $\mathcal{E}$ or $H$; (iii) $\theta$ is a user-provided, possibly partial substitution; and (iv) $\theta \gamma$ satisfies $\Gamma^{\prime}$, i.e., for each $t=t^{\prime}$ in the hypothesis' condition $\Gamma^{\prime}, t \theta \gamma!{\overrightarrow{\mathcal{F}_{\bar{X}_{U}}} \cup \vec{H}_{e_{U}}^{+}}={ }_{B_{0}} t^{\prime} \theta \gamma!{\overrightarrow{\mathcal{E}_{\bar{X}_{U}}} \breve{H}_{e_{U}}^{+}}$. Since $=_{-}$is assumed commutative, the user chooses $\sqrt{29}$ the term $u$ in the conditional equation ( $u$ is displayed on the left of the equation, but could syntactically appear on the right) such that $u \theta$ will be $B_{0}$-matched by $w$ at position $p$. Since $\Gamma^{\prime} \rightarrow u=v$ may be a non-executable hypothesis, there may be extra variables in $v$ and/or $\Gamma^{\prime}$ not appearing in $u$, so that specifying the partial substitution $\theta$ may be necessary. In simple cases $\theta$ may not be needed and $\gamma$ may be found just by $B_{0}$-matching the goal's subterm $w$ with the pattern $u$. Rule $\mathbf{E Q}$ allows performing one step of equational inference with a possibly conditional equational hypothesis in a user-guided manner.

Cut.

$$
\frac{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Gamma^{\prime} \quad[\bar{X}, \mathcal{E}, H] \Vdash \Gamma, \Gamma^{\prime} \rightarrow \Lambda}{[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda}
$$

where $\Gamma^{\prime}$ is a conjunction of equalities and $\operatorname{vars}\left(\Gamma^{\prime}\right) \subseteq \operatorname{vars}(\Gamma \rightarrow \Lambda)$. Cut can be viewed as a generalized modus ponens rule, since when $\Gamma \equiv \mathrm{T}$ it actually becomes modus ponens. In relation to ICC, we can regard ICC as a modus ponens rule internal to the goal $\Gamma \rightarrow \Lambda$ viewed as an implication; whereas Cut is a modus ponens rule external to the goal $\Gamma \rightarrow \Lambda$ viewed as a formula, where the user has complete freedom to choose a suitable $\Gamma^{\prime}$ that will help in proving the original goal.

[^19]Example 10. Consider an equational theory $\mathcal{E}$ containing the multiset specification in Example 1 in Section 2.9. For concreteness, let us identify the sort Elt with the sort Nat for the Peano natural numbers, to which we have added an equality predicate ${ }_{-}=\cdot_{-}$on naturals. The membership predicate $\epsilon_{\ldots}$ is defined by the equations: $n \in \varnothing=$ false, $n \in m=n \cdot=\cdot m$, and $n \in(m \cup U)=(n \cdot=\cdot m)$ or $n \in U$, with $n, m$ of sort Nat and $U, V$ of sort NeMSet. Consider now the goal:

$$
n \in V=\text { false }, n \cup U=V \rightarrow \perp
$$

We can prove this goal by applying Cut with $\Gamma^{\prime}=n \in(n \cup U)=n \in V$. That is, we need to prove the subgoals: (1) $n \in V=$ false, $n \cup U=V \rightarrow n \in(n \cup U)=n \in V$, and (2) $n \in V=$ false, $n \cup U=V, n \in(n \cup U)=n \in V \rightarrow \perp$. Subgoal (1) can be discharged by ICC followed by EPS. Appliying EPS to subgoal (2) we get (2') $n \in V=$ false, $n \cup U=$ $V$, true $=n \in V \rightarrow \perp$, which can also be discharged by ICC followed by EPS.

The main property about the above inference system is the following Soundness Theorem, whose proof is given in Appendix $B$

Theorem 1 (Soundness Theorem). If a closed proof tree can be built from a goal of the form $[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda$, then $[\bar{X}, \mathcal{E}, H] \mid \Gamma \rightarrow \Lambda$.

Although the Soundness Theorem is stated in full generality, in practice, of course, its main application will be to initial goals of the form $[\varnothing, \mathcal{E}, \varnothing] \Vdash \Gamma \rightarrow \Lambda$ or $[\varnothing, \mathcal{E}, \varnothing] \Vdash$ $(\exists \chi)(\Gamma \rightarrow \Lambda)$.

The Automated vs. Interactive Tradeoff. This section has presented eleven goal simplification inference rules that exploit the induction hypotheses and the various symbolic techniques explained in Section 2 to simplify goals as much as possible. It has also presented nine inductive inference rules to be used primarily in intercative mode, although some could be automated. There is in fact a tradeoff between automation and interaction. A key goal of the inference system is to allow "seven league boots" proof steps. The NuITP allows the user to fine tune the tradeoff between automation and interaction by choosing between applying one inference rule at a time or combining an inference rule step with subsequent goal simplification steps. Furthermore, the NuITP already provides basic support for user-defined proof strategies through a simple strategy language that, as more experience is gained, will be extended in the future. Finally, a fully automated use of the NuITP, in which the tool with a chosen proof strategy is used as a backend by other tools is illustrated by the DM-Check tool [7]8] and is envisioned for other tools.

## 5 Other Inductive Proof Examples

Six additional examples further illustrate the use of the simplification and inductive rules and show the advantages of the multiclause representation.

1. Using Lemmas. We illustrate how the LE rule can help in proving a conjecture. The conjecture in question is the original formula in Example 3, which applying the EPS and ICC simplification rules in, respectively, Examples 3 and 6 became the considerably simpler goal:

$$
[\varnothing, \mathcal{N P}, \varnothing] \Vdash x * x=s(0), y=0 \rightarrow s(0)=x .
$$

We can apply the CAS rule to variable $x$ with generator set $\{0, s(0), s(s(z))\}$ to get the following three subgoals:

$$
\begin{gathered}
{[\varnothing, \mathcal{N} \mathcal{P}, \varnothing] \Vdash 0 * 0=s(0), y=0 \rightarrow s(0)=0} \\
{[\varnothing, \mathcal{N} \mathcal{P}, \varnothing] \Vdash s(0) * s(0)=s(0), y=0 \rightarrow s(0)=s(0)} \\
{[\varnothing, \mathcal{N} \mathcal{P}, \varnothing] \Vdash s(s(z)) * s(s(z))=s(0), y=0 \rightarrow s(0)=s(s(z))}
\end{gathered}
$$

The EPS rule automatically discharges the first two. To prove the third, we assume as already proved the commutativity of natural number addition in Peano notation - a property that was proved in Example 8 for the "twice as fast" definition of addition, and whose detailed proof for the standard definition of addition we leave to the reader- and use the $\mathbf{L E}$ rule to get the goal:

$$
[\varnothing, \mathcal{N P},\{n+m=m+n\}] \Vdash s(s(z)) * s(s(z))=s(0), y=0 \rightarrow s(0)=s(s(z))
$$

Thanks to the fact that the commutativity equation $n+m=m+n$ can be applied using ordered rewriting, EPS simplification of this goal can use the lemma plus the equations for $*$ and + to first transform the equation $s(s(z)) * s(s(z))=s(0)$ into the equation $s(s(s(s((s(s(z)) * z)+z))))=s(0)$, which is further transformed to $\perp$ by means of the $\mathcal{N} \mathcal{P}^{=}$-rules $s(n)=s(m) \rightarrow n=m$ and $s(n)=0 \rightarrow \perp$, thus discharging the goal and finishing the proof.

An intriguing thought about the $n+m=m+n$ lemma is that, instead of applying it by ordered rewriting, it could have been "internalized" after the fact as a commutativity axiom which is added to the theory $\mathcal{N P}$. More generally, any associativity and/or commutativity properties that have been proved as lemmas for some defined binary function symbol $f$ could be so internalized, provided the module's oriented equations $\overrightarrow{\mathcal{E}}$ remain RPO-terminating. This internalization process is already supported by the NuITP prover for both orientable equations and associativity or commutativity axioms proved as lemmas [18] (for a broader view of internalization and its semantic foundations see [57]).
2. Multiplicative Cancellation. This example is borrowed from [49]. We wish to prove the cancellation law for natural number multiplication

$$
x * z^{\prime}=y * z^{\prime} \Rightarrow x=y
$$

where $z^{\prime}$ ranges over non-zero natural number while $x$ and $y$ range over natural numbers. We specify natural number addition and multiplication as associative-commutative operators, as well as the $>$ predicate, in a theory $\mathcal{N}$ having a subsort relation $\mathrm{NzNat}<\mathrm{Nat}$ of non-zero numbers as subset of all naturals (see Appendix Afor a detailed specification of $\mathcal{N}$ ). Of course, since the proof of the reverse implication $x=y \Rightarrow x * z^{\prime}=y * z^{\prime}$ follows trivially by simplification with the (ICC) rule, what we are really proving is the equivalence $x * z^{\prime}=y * z^{\prime} \Leftrightarrow x=y$. Therefore, using the (ERL) and (ERR) rules, once the above cancellation rule has been proved, the rewrite rule $x * z^{\prime}=y * z^{\prime} \rightarrow x=y$ can be added to the equality predicate theory $\overrightarrow{\mathcal{N}}=\left(\mathcal{N}\right.$ has no $U$ axioms, i.e., $\left.\overrightarrow{\mathcal{N}}_{U}^{=}=\overrightarrow{\mathcal{N}}=\right)$ to obtain a more powerful version of the (EPS) simplification rule.
We begin with the goal:

$$
G:[\varnothing, \mathcal{N}, \varnothing] \Vdash x * z^{\prime}=y * z^{\prime} \rightarrow x=y
$$

After applying the rule GSI to the variable $x$ with the $B_{0}$-generator set $\left\{0,1+x_{1}\right\}$ and simplifying by EPS we obtain:

$$
\begin{gathered}
G_{1}:[\varnothing, \mathcal{N}, \varnothing] \Vdash 0=y * z^{\prime} \rightarrow 0=y \\
G_{2}:\left[\left\{\bar{x}_{1}\right\}, \mathcal{N}, \bar{x}_{1} * z^{\prime}=y * z^{\prime} \rightarrow \bar{x}_{1}=y\right] \Vdash z^{\prime}+\left(\bar{x}_{1} * z^{\prime}\right)=y * z^{\prime} \rightarrow \bar{x}_{1}+1=y
\end{gathered}
$$

We first prove $G_{1}$ by: (a) applying the CAS rule to variable $y$ with the $B_{0}$-generator set $\left\{0, y^{\prime}\right\}$, where $y^{\prime}$ has the non-zero natural sort $N z N a t$; and (b) applying the EPS rule to obtain:

$$
\begin{gathered}
G_{1.1}:[\varnothing, \mathcal{N}, \varnothing] \Vdash 0=0 \rightarrow 0=0 \\
G_{1.2}:[\varnothing, \mathcal{N}, \varnothing] \Vdash 0=y^{\prime} * z^{\prime} \rightarrow 0=y^{\prime}
\end{gathered}
$$

To solve $G_{1.1}$, apply EPS to obtain $\top$. To solve $G_{1.2}$, apply VA to the term $y^{\prime} * z^{\prime}$ which has least sort NzNat to obtain:

$$
G_{1.2 .1}:[\varnothing, \mathcal{N}, \varnothing] \Vdash 0=z^{\prime \prime}, z^{\prime \prime}=y^{\prime} * z^{\prime} \rightarrow 0=y^{\prime}
$$

where $z^{\prime \prime}$ also has sort $N z N a t$. Finally apply CVUL to obtain $\top$, since the equation $0=z^{\prime \prime}$ has no unifiers. This finishes the proof of $G_{1}$. We now prove $G_{2}$ by: (a) applying the CAS rule to variable $y$ with $B_{0}$-generator set $\left\{0, y_{1}+1\right\}$; and (b) applying the EPS rule to obtain:

$$
\begin{gathered}
G_{2.1}:\left[\left\{\bar{x}_{1}\right\}, \mathcal{N}, \bar{x}_{1} * z^{\prime}=y * z^{\prime} \rightarrow \bar{x}_{1}=y\right] \Vdash z^{\prime}+\left(\bar{x}_{1} * z^{\prime}\right)=0 \rightarrow \bar{x}_{1}+1=0 \\
G_{2.2}:\left[\left\{\bar{x}_{1}\right\}, \mathcal{N}, \bar{x}_{1} * z^{\prime}=y * z^{\prime} \rightarrow \bar{x}_{1}=y\right] \Vdash \begin{array}{c}
z^{\prime}+\left(\bar{x}_{1} * z^{\prime}\right)=\left(y_{1} * z^{\prime}\right)+z^{\prime} \\
\rightarrow \bar{x}_{1}+1=y_{1}+1
\end{array}
\end{gathered}
$$

To solve $G_{2.1}$, apply VA to the term $z^{\prime}+\left(\bar{x}_{1} * z^{\prime}\right)$ which has least sort $N z N a t$ to obtain:

$$
G_{2.1 .1}:\left[\left\{\bar{x}_{1}\right\}, \mathcal{N}, \bar{x}_{1} * z^{\prime}=y * z^{\prime} \rightarrow \bar{x}_{1}=y\right] \Vdash \begin{gathered}
z^{\prime}+\left(\bar{x}_{1} * z^{\prime}\right)=z^{\prime \prime}, z^{\prime \prime}=0 \\
\rightarrow \bar{x}_{1}+1=0
\end{gathered}
$$

where $z^{\prime \prime}$ also has sort $N z N a t$. As in $G_{1.2 .1}$, apply CVUL to obtain T. Finally, to solve $G_{2.2}$, we apply ERL and $\mathbf{E R R}$ with the equivalence $z_{1}+z_{2}=z_{1}+z_{3} \Leftrightarrow z_{2}=z_{3}$ (which can be proved by variant satisfiability) to obtain:

$$
G_{2.2 .1}:\left[\left\{\bar{x}_{1}\right\}, \mathcal{N}, \bar{x}_{1} * z^{\prime}=y * z^{\prime} \rightarrow \bar{x}_{1}=y\right] \Vdash \bar{x}_{1} * z^{\prime}=y_{1} * z^{\prime} \rightarrow \bar{x}_{1}=y_{1}
$$

But note that a proof of $G_{2.2 .1}$ immediately follows by CS. In summary, we completed the proof after 14 applications of our inference rules.
3. Proving Disequalities. Consider again the theory $\mathcal{N}$ used in the above Multiplicative Cancellation example and described in detail in Appendix We now wish to prove the inductive validity of the implication:

$$
n>1=\text { true } \Rightarrow(n+n \neq n \wedge n * n \neq n) .
$$

That is, the inductive validity of the clauses:

$$
n>1=\text { true }, n+n=n \rightarrow \perp
$$

and

$$
n>1=\text { true }, n * n=n \rightarrow \perp .
$$

Since, as pointed out in Appendix the subtheory $\mathcal{N}_{1}$ with constants 0,1 , true and false, $>$, and all typings for operator + , and the equations for + and $>$ is FVP, and has a subsignature of constructors with 0,1 , true, false, and the smallest typing for the $A C$ operator + , the first clause can be automatically simplified to $T$ in two different ways: either by application of the VARSAT rule, or -since $n>1=$ true $\wedge n+n=n$ has no variant unifiers- by applying instead the CVUL rule.
To prove the second clause, we can apply to the equation $n>1=$ true in its condition the CVUL rule. This equation has the single constructor variant unifier $\left\{n \mapsto 1+n^{\prime}\right\}$, where $n^{\prime}$ has sort $N z N a t$, so we get the goal:

$$
\left(n^{\prime}+1\right) *\left(n^{\prime}+1\right)=n^{\prime}+1 \rightarrow \perp
$$

which is simplified by the EPS rule to the goal:

$$
n^{\prime}+n^{\prime}+\left(n^{\prime} * n^{\prime}\right)=n^{\prime} \rightarrow \perp
$$

which applying the VA rule yields the goal:

$$
n^{\prime}+n^{\prime}+m^{\prime}=n^{\prime}, m^{\prime}=n^{\prime} * n^{\prime} \rightarrow \perp
$$

with $m^{\prime}$ of sort $N z N a t$, which automatically simplifies to $\top$ by applying the CVUL rule to the equation $n^{\prime}+n^{\prime}+m^{\prime}=n^{\prime}$, since that equation has no variant unifiers.
4. Reversing Palindromes. This example extends the theory $\mathcal{L}$ in Example 9 on reversing (non-empty) lists of elements. It comes with the added bonus of illustrating the inductive congruence closure (ICC) simplification rule. We extend $\mathcal{L}$ by: (i) automatically extending it to $\mathcal{L}^{=}$, where equationally-defined equality predicates have been added 30 and (ii) adding also a palindrome Boolean predicate on (non-empty) lists pal : List $\rightarrow$ Bool, defined (with the same typing for variables as in Example 9) by the following equations oriented as rules: $[3]: \operatorname{pal}(x)=\operatorname{true},[4]: \operatorname{pal}(x \cdot x)=\operatorname{true},[5]: \operatorname{pal}(x \cdot Q \cdot x)=\operatorname{pal}(Q)$, [6]: $\operatorname{pal}(x \cdot y)=$ false if $(x=y)=$ false, [7]: $\operatorname{pal}(x \cdot Q \cdot y)=$ false if $(x=y)=$ false. The goal we want to prove is:

$$
\operatorname{pal}(L)=\operatorname{true} \rightarrow \operatorname{rev}(L)=L
$$

First, of all, using the $\mathbf{L E}$ rule, we can add to this goal the lemma $\operatorname{rev}(Q \cdot y)=y \cdot \operatorname{rev}(Q)$ already proved in Example 9 , which, with the order on symbols $($ rev $)>\left(\_\cdot\right)$, is reductive and can therefore be listed as rule $[8]: \operatorname{rev}(Q \cdot y) \rightarrow y \cdot \operatorname{rev}(Q)$. Let us apply rule NI, choosing $\operatorname{pal}(L)$ as our focus narrowex. Note that the narrowings with rules [6]-[7] generate true $=$ false the corresponding premises of their subgoals, so those subgoals simplify to $T$. The subgoals obtained by narrowing with rules [3] (resp. [4]) simplify to $T$ thanks to rule [1] (resp. rules [1] and [2]) for rev. The only non-trivial case is the subgoal obtained by narrowing with rule [5] and substitution $\alpha=\{L \mapsto y \cdot P \cdot y, Q \mapsto P, x \mapsto y\}$, yielding subgoal

$$
\operatorname{pal}(\bar{P})=\operatorname{true} \rightarrow \operatorname{rev}(\bar{y} \cdot \bar{P} \cdot \bar{y})=\bar{y} \cdot \bar{P} \cdot \bar{y} .
$$

which, using the rev equations and Lemma [8], simplifies to

$$
\operatorname{pal}(\bar{P})=\operatorname{true} \rightarrow \bar{y} \cdot \operatorname{rev}(\bar{P}) \cdot \bar{y}=\bar{y} \cdot \bar{P} \cdot \bar{y}
$$

[^20]and has induction hypothesis
$$
\operatorname{pal}(\bar{P})=\operatorname{true} \rightarrow \operatorname{rev}(\bar{P})=\bar{P}
$$

We can further simplify this remaining subgoal by ICC simplification. The congruence closure of $\operatorname{pal}(\bar{P})=$ true is just the rule $\operatorname{pal}(\bar{P}) \rightarrow$ true, which cannot be further simplified. The induction hypothesis $\operatorname{pal}(\bar{P})=\operatorname{true} \rightarrow \operatorname{rev}(\bar{P})=\bar{P}$, being ground and having $\operatorname{rev}(\bar{P})>\bar{P}$, is orientable as a rewrite rule $\operatorname{pal}(\bar{P})=\operatorname{true} \rightarrow(\operatorname{rev}(\bar{P}) \rightarrow \bar{P})$ in $\vec{H}_{e_{U}}^{\oplus}$. Furthermore: (i) its lefthand side does match the subterm $\operatorname{rev}(\bar{P})$ in the subgoal's conclusion; and (ii) its condition is satisfied with the congruence closure $\operatorname{pal}(\bar{P}) \rightarrow$ true. Therefore, thanks to the ICC rule, the entire goal simplifies to $\top$, finishing the proof of our original goal by a single application of NI followed by simplification.
5. Simplifying Conjectures by Rewriting with Non-Horn Hypotheses. As explained in Section 3.2, we are using a substantial set of induction hypothesis as rewrite rules $\vec{H}_{e_{U}}^{+}$ to simplify conjectures. Some of the hypotheses so used can be non-Horn, that is, clauses $\Upsilon \rightarrow \Delta$ where $\Delta$ has more than one disjunct. But we have not yet seen any examples illustrating the power of simplification with non-Horn hypotheses. A simple example illustrating such power is provided by the well-known unsorted theory $\mathcal{N}_{>}$defining the order relation on the Peano natural numbers, defined by the equations, oriented as rules, [1]:0>n false, [2]: $s(n)>0 \rightarrow$ true, and [3]: $s(n)>s(m) \rightarrow n>m$ (which has the subcall $n>m$ ). We want to use $\mathcal{N}_{>}$to prove the trichotomy law:

$$
x>y=\text { true } \vee x=y \vee y>x=\text { true }
$$

We can apply the NI rule to the narrowex $x>y$. Narrowing with rule [2], the leftmost equation in the disjunction becomes true $=$ true, which allows easily discharging the generated subgoal by EPS simplification. Narrowing with rule [1] and substitution $\alpha_{1}=\left\{x \mapsto 0, y \mapsto y^{\prime}, n \mapsto y^{\prime}\right\}$, we generate the subgoal false $=$ true $\vee 0=y^{\prime} \vee y^{\prime}>0=$ true, which by $\overrightarrow{\mathcal{E}}^{=}$-simplification becomes the subgoal $0=y^{\prime} \vee y^{\prime}>0=$ true, which can be easily discharged by applying again the NI rule to the narrowex $y^{\prime}>0$, to which only rule [2] can be applied, making the second disjunct true $=$ true, which allows easily discharging of the generated subgoal by $\overrightarrow{\mathcal{E}}^{=}$-simplification. Finally, narrowing with rule [3] and substitution $\alpha_{3}=\left\{x \mapsto s\left(x^{\prime}\right), y \mapsto s\left(y^{\prime}\right), n \mapsto x^{\prime}, m \mapsto y^{\prime}\right\}$, we get subgoal (3): $\overline{x^{\prime}}>\overline{y^{\prime}}=$ true $\vee s\left(\overline{x^{\prime}}\right)=s\left(\overline{y^{\prime}}\right) \vee s\left(\overline{y^{\prime}}\right)>s\left(\overline{x^{\prime}}\right)=$ true, which $\overrightarrow{\mathcal{E}}_{\left\{\overline{\left.x^{\prime}, y^{\prime}\right\}}\right.}^{=}$-simplifies to $\overline{x^{\prime}}>\overline{y^{\prime}}=$ true $\vee \overline{x^{\prime}}=\overline{y^{\prime}} \vee \overline{y^{\prime}}>\overline{x^{\prime}}=$ true, and we also get the induction hypothesis $H_{3} \equiv \overline{x^{\prime}}>\overline{y^{\prime}}=$ true $\vee \overline{x^{\prime}}=\overline{y^{\prime}} \vee \overline{y^{\prime}}>\overline{x^{\prime}}=$ true, which in $\vec{H}_{e_{U}}^{\oplus}$ becomes the ground rewrite rule $\left(\overline{x^{\prime}}>\overline{y^{\prime}}=\right.$ true $\vee \overline{x^{\prime}}=\overline{y^{\prime}} \vee \overline{y^{\prime}}>\overline{x^{\prime}}=$ true $) \rightarrow$. But then, the simplified subgoal (3) is immediately discharged by EPS simplification, thanks to this rule in $\vec{H}_{e_{U}}^{+\oplus}$.
6. Reasoning with Multiclauses. Up to now most examples have involved clauses. The reader may reasonably wonder whether the extra generality of supporting multiclauses is worth the trouble. The purpose of this simple example is to dispel any such qualms: multiclauses can afford a substantial economy of thought and support shorter proofs. The example is unsorted and well known: a slight extension of the theory $\mathcal{N}_{>}$just used for illustrating the simplification of conjectures with non-Horn hypothesis. It comes with the added bonuses of illustrating equationally-defined equality predicates (see Section 2.5) and the inductive congruence closure (ICC) simplification rule.

First of all, we extend the theory $\mathcal{N}_{>}$to its -automatically generated- protecting extension $\mathcal{N}_{>}^{=}$, which adds a commutative, equationally defined Boolean equality predicate ${ }_{-}={ }_{-}$In $\mathcal{N}_{>}^{=}$, the equality predicate $=_{-}$for sort the Nat of naturals is defined by three rules ${ }^{31}$ namely, $n=n \rightarrow$ true, $0=s(n) \rightarrow$ false, and $s(n)=s(m) \rightarrow n=m$. We then further extend $\mathcal{N}_{>}^{=}$by declaring the $\geqslant$predicate, defined by the single rule: [4]: $n \geqslant m=(n>$ $m$ or $n=m)$. Two basic properties about $>$ and $\geqslant$ that we wish to prove as lemmas are:

$$
x>y=\text { true } \rightarrow s(x)>y=\text { true } \quad \text { and } \quad x>y=\text { true } \rightarrow y \geqslant x=\text { false } .
$$

We can of course prove them as separate lemmas. But we can bundle them together and prove instead the single multiclause:

$$
x>y=\text { true } \rightarrow(s(x)>y=\text { true } \wedge y \geqslant x=\text { false }) .
$$

We can, for example, apply NI to the focus narrowex $x>y$. The subgoal obtained by narrowing with rule [1] is discharged by simplification, since we get false $=$ true in the premise. Narrowing with rule [2] and substitution $\alpha_{2}=\left\{x \mapsto s\left(n^{\prime}\right), n \mapsto n^{\prime}, y \mapsto 0\right\}$ yields the subgoal true $=$ true $\rightarrow\left(s\left(s\left(n^{\prime}\right)\right)>0=\right.$ true $\wedge 0 \geqslant s\left(n^{\prime}\right)=$ false, which also simplifies to $T$ and is likewise discharged. The interesting goal is the one obtained by narrowing with rule [3] and substitution $\alpha_{2}=\left\{x \mapsto s\left(n^{\prime}\right), n \mapsto n^{\prime}, y \mapsto s\left(m^{\prime}\right), m \mapsto m^{\prime}\right\}$, namely,

$$
\overline{n^{\prime}}>\overline{m^{\prime}}=\text { true } \rightarrow\left(s\left(s\left(\overline{n^{\prime}}\right)\right)>s\left(\overline{m^{\prime}}\right)=\text { true } \wedge s\left(\overline{m^{\prime}}\right) \geqslant s\left(\overline{n^{\prime}}\right)=\text { false }\right) .
$$

which simplifies to:

$$
\overline{n^{\prime}}>\overline{m^{\prime}}=\text { true } \rightarrow\left(s\left(\overline{n^{\prime}}\right)>\overline{m^{\prime}}=\text { true } \wedge\left(\overline{m^{\prime}}>\overline{n^{\prime}} \text { or } \overline{m^{\prime}}=\overline{n^{\prime}}\right)=\text { false }\right)
$$

and has the following two simplified induction hypotheses:

$$
\overline{n^{\prime}}>\overline{m^{\prime}}=\text { true } \rightarrow s\left(\overline{n^{\prime}}\right)>\overline{m^{\prime}}=\text { true } \quad \text { and } \quad \overline{n^{\prime}}>\overline{m^{\prime}}=\text { true } \rightarrow\left(\overline{m^{\prime}}>\overline{n^{\prime}} \text { or } \overline{m^{\prime}}=\overline{n^{\prime}}\right)=\text { false }
$$

The congruence closure of the goal's premise is quite immediate, namely, the rewrite rule $\overline{n^{\prime}}>\overline{m^{\prime}} \rightarrow$ true, which cannot be further simplified. Since the two hypotheses are reductive, they are orientable as rewrite rules $\overline{n^{\prime}}>\overline{m^{\prime}}=\operatorname{true} \rightarrow\left(s\left(\overline{n^{\prime}}\right)>\overline{m^{\prime}} \rightarrow\right.$ true $)$ and $\overline{n^{\prime}}>\overline{m^{\prime}}=$ true $\rightarrow\left(\left(\overline{m^{\prime}}>\overline{n^{\prime}}\right.\right.$ or $\left.\overline{m^{\prime}}=\overline{n^{\prime}}\right) \rightarrow$ false $)$, which belong to $\vec{H}_{e_{U}}$ and, a fortiori, to $\vec{H}_{e_{U}}^{\oplus}$. But since: (i) their lefhand sides match respective subterms of the subgoal's conclusion, and (ii) their condition is satisfied by the congruence closure $\overline{n^{\prime}}>\overline{m^{\prime}} \rightarrow$ true, the ICC rule simplifies the subgoal to $T$, thus finishing the (joint) proof of both lemmas by a single application of NI to their multiclause bundling, followed by simplification.

An even simpler and very common opportunity of bundling clauses into multiclauses arises when trying to prove several conjectures that are themselves equations, in which case a multiclause is just a conjunction of equations. Let us focus for simplicity on two such equations, $e_{1}(x, y)$ and $e_{2}\left(x^{\prime}, y^{\prime}\right)$, involving variables $x, x^{\prime}$ of sort $s_{1}$ and $y, y^{\prime}$ of sort $s_{2}$. Since we know that $T_{\mathcal{E}}=e_{1}(x, y)$ iff $T_{\mathcal{E}}=e_{1}\left(x^{\prime}, y^{\prime}\right)$, then, $T_{\mathcal{E}}=e_{1}(x, y)$ and $T_{\mathcal{E}}=e_{2}\left(x^{\prime}, y^{\prime}\right)$ hold, i.e., both conjectures are valid, iff $T_{\mathcal{E}}=e_{1}\left(x^{\prime}, y^{\prime}\right) \wedge e_{2}\left(x^{\prime}, y^{\prime}\right)$ does. The moral of this little Gedankenexperiment is that, to take full advantage of bundling several clauses into a multiclause, we should first rename some of their variables, so that the different conjuncts share as many variables as possible. In this way, we may achieve the proverbial -yet, not politically correct - objective of killing as many birds as possible with a single stone.

[^21]
## 6 Related Work and Conclusions

As already mentioned, this work combines features from automated, e.g., [58|28|39|41|5|10|16] and explicit, e.g., [42|30|34|14|27|15|38|36|31| equational inductive theorem proving, as well as some features from first-order superposition theorem proving [667|72], in a novel way. In the explicit induction area, the well-known ACL2 prover [43] should also be mentioned. ACL2 does not directly support inductive reasoning about general algebraic specifications. It does instead support very powerful inductive reasoning about LISP-style data structures. One way to relate ACL2 to the above-mentioned explicit induction equational inductive provers is to view it as a very powerful domain-specific explicit induction equational theorem prover for recursive functions defined over LISP-style data structures ${ }_{2}^{32}$

Some of the automatable techniques presented here have been used in some fashion in earlier work, but, to the best of my knowledge, others have not. For example, congruence closure is used in many provers, but congruence closure modulo is considerably less used, and order-sorted congruence closure modulo is here used for the first time. Contextual rewriting goes back to the Boyer-More prover [11], later extended to ACL2 [43], and has also been used, for example, in RRL [16] and in Spike [10]; and clause subsumption and ordered rewriting are used in most automated theorem provers, including inductive ones. Equational simplification is used by most provers, and ordered rewriting is used by most first-order and inductive automatic provers and by some explicit induction ones; but to the best of my knowledge simplification with equationally-defined equality predicates modulo axioms $B_{0}$ was only previously used in [62], although in the much easier free case equality predicates have been used to specify "consistency" properties of data types in, e.g., [39]16]. To the best of my knowledge, neither constructor variant unification nor variant satisfiability have been used in other general-purpose provers, although variant unification is used in various cryptographic protocol verification tools, e.g., [23|48]. Combining all these techniques, and doing so in the very general setting of conditional order-sorted equational theories -which subsume unsorted and manysorted ones as special cases- and modulo any associativity and/or commutativity and/or identity axioms appears to be new.

The combination of features from automated and explicit-induction theorem proving offers the short-term possibility of an inference subsystem that can be automated as a practical oracle for inductive validity of VCs generated by other tools. This automation, by including most of the formula simplification rules, would allow users to focus on applying just the 9 inductive inference rules. Of these, the NI rule and (a special case of) the VA rule offer the prospect of being easily automatable ${ }^{33}$ bringing us closer to the goal of achieving a practical synthesis between interactive and automated inductive theorem proving. As the experience of using a subset of the formula simplification rules to discharge VCs generated by the reachability logic theorem prover reported in [49] as well as the more recent experience of using the NuITP as a backend to discharge inductive VCs in the DM-Check tool [7|8] suggests, such a synthesis could provide an effective way for a wide variety of other tools to use an inductive theorem prover as an automatic "backend" VC verifier. Strategies will play a key role in achieving this goal. The NuITP

[^22]already provides some support for defining and using strategies, but this is an area that should be further developed.

Another area that needs further development is that of proof certification. The current version of the NuITP supports the saving of proof scripts and the display of proof trees in IATEX notation. Full proof certification is possible, but it will require very substantial efforts. A key challenge is the large body of symbolic algorithms involved that need to be certified. For example, only very recently has certification for unsorted associativecommutative unification become possible after a very large effort formalizing and verifying Stickel's algorithm in the PVS prover [1]. Several inference rules use either ordersorted $B$-unification for any combination of associative and/or commutative and/or unit axioms, or variant $E \cup B$-unification, for which no machine-assisted formalizations such as that in [1] currently exist to the best of my knowledge. Some partial certification of $B$ - and $E \cup B$-unifiers is certainly possible and achievable in the near future, namely, certification that a $B$ - or $E \cup B$-unifier is correct. The challenging part is the certification of completeness: that the set of unifiers provided by the unification algorithm covers as instances all other unifiers for the given unification problem. In the near future, since a good number of inference rules are based on rewriting modulo axioms $B$ in an ordersorted equational theory, the correctness of those rewriting steps as equality steps could be certified using the certification method developed for that purpose in [63]. This would also allow the "easy" part of unifier certification. Included also in the need for certification are the requirements made on the equational theory $\mathcal{E}$, such as ground convergence and sufficient completeness. Here partial certification is already available thanks to other exisiting Maude formal tools such as Maude's Church-Rosser Checker [22], Termination Tool [19|20] and Sufficient Completeness Checker [37]. But, again, full certification would require substantial new efforts. For example, computation of critical pairs in [22] requires $B$-unification, which itself would have to be certified.

In summary, what this paper reports on is a novel combination of inductive theorem proving techniques to prove properties of equational programs under very general assumptions: the equational programs can use conditional equations, can execute modulo structural axioms $B$ such as associativity and/or communtativity and/or unit element axioms, and can have types and subtypes. The main goal is to combine as much as possible features of automatic and interactive inductive theorem proving to make proofs shorter, while still giving the user complete freedom to guide the proof effort. The experience already gained with the NuITP is quite encouraging; but there is much work ahead. First, as mentioned in Footnote 23, the requirement of constructors being free modulo $B_{0}$ should be relaxed. Second, strategies more powerful than those currently supported by the NuITP should be developed and illustrated with examples. Third, a richer collection of examples and challenging case studies as well as libraries of already verified equational programs should be developed. Fourth, the use of the NuITP in automated mode as a backed should be applied to a variety of other formal tools. Fifth, as mentioned above, substantial work is needed in proof certification, which realistically should begin with various kinds of partial certification as steps towards full certification. In these and other ways, additional evidence for the usefulness of the current inference system will become available, and useful extensions and improvements of the inference system itself are likely to be found.

Acknowledgements. I warmly thank Stephen Skeirik for his contributions to the conference paper [49], which, as explained in Section 1] has been further developed in sub-
stantial ways in this paper. Since, due to other professional obligations, Dr. Skeirik was not able to participate in these new developments, he has expressed his agreement on my being the sole author of the present paper. I cordially thank the reviewers of this paper as well as Francisco Durán, Santiago Escobar, Ugo Montanari and Julia Sapiña for their excellent suggestions for improvement, which have led to a better and clearer exposition. Furthermore, the collaboration on the NuITP with Drs. Durán, Escobar and Sapiña has, as already mentioned, both further advanced the inference system and demonstrated its effectiveness on substantial examples. This work has been partially supported by NRL under contracts N00173-17-1-G002 and N0017323C2002.

## A The Natural Numbers Theory $\boldsymbol{N}$

The natural number theory used in the multiplicative cancellation example of Section 5 is borrowed from [49] and has the following Maude specification:

```
fmod NATURAL is protecting TRUTH-VALUE .
    sorts Zero NzNat Nat .
    subsorts Zero NzNat < Nat .
    op 0 : -> Zero [ctor].
    op 1 : -> NzNat [ctor] .
    op _+_ : NzNat NzNat -> NzNat [ctor assoc comm] .
    op _+_ : NzNat Nat -> NzNat [ assoc comm] .
    op _+_ : Nat NzNat -> NzNat [ assoc comm] .
    op _+_ : Nat Nat -> Nat [ assoc comm] .
    op _*_ : NzNat NzNat -> NzNat [ assoc comm] .
    op _*_ : Nat Nat -> Nat [ assoc comm].
    op _>_ : Nat Nat -> Bool .
    vars X Y Z : Nat . var X' : NzNat .
    eq X + 0 = X [variant].
    eq X* 0 = 0.
    eq X * 1 = X .
    eq X * (Y + Z) = (X * Y) + (X * Z).
    eq X + X' > X = true [variant].
    eq X > X + Y = false [variant] .
endfm
```

Fig. 1. Natural Number Theory Specification.

Note that we have a "sandwich" of theories $\mathcal{N}_{\Omega} \subseteq \mathcal{N}_{1} \subseteq \mathcal{N}$, where $\mathcal{N}_{\Omega}$ is given by the constants true and false in TRUTH-VALUE plus the operators marked as ctor, including the first typing for + , and that $\mathcal{N}_{1}$ is the FVP theory extending $\mathcal{N}_{\Omega}$ with the remaining typings for + , the $>$ predicate, the equation for $\theta$ as identity element for + , and the two equations for $>$.

## B Proof of the Soundness Theorem

We need to prove that, under the theorem's assumptions on $\mathcal{E}$, if $[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda$ has a closed proof tree, then $[\bar{X}, \mathcal{E}, H] \models \Gamma \rightarrow \Lambda$. We reason by contradiction, and assume that such an implication does not hold. This means that there is a goal $[\bar{X}, \mathcal{E}, H] \Vdash \Gamma \rightarrow \Lambda$ having a closed proof tree of smallest depth $d$ possible and such that $[\bar{X}, \mathcal{E}, H] \not \models \Gamma \rightarrow \Lambda$. That is, any closed proof tree of any goal having depth less than $d$ proves a goal that is valid in its associated theory. We then reach a contradiction by considering the inference
rule applied at the root of the tree. Before reasoning by cases considering each inference rule, we prove three lemmas that will be useful in what follows. The statement of the first lemma might be deceptive without some explanation of its purpose. One might easily assume that $(\Sigma, E)$ will be used in practice as an order-sorted equational theory $\mathcal{E}$ where we want to prove inductive theorems about its initial model $T_{\mathcal{E}}$. This is $a$ possible use of the lemma, but the intention is to use it in the following, more general sense. Recall the following definition of executable inductive hypotheses:

$$
\vec{H}_{e_{U}}^{+}=\vec{H}_{e_{U}} \cup \vec{H}_{w u_{U}} \cup \vec{H}_{v, e}^{=}
$$

and note that $\vec{H}_{e_{U}} \cup \vec{H}_{w u_{U}}$ denotes a set of $\Sigma(\bar{X})$-rewrite rules orienting conditional equations, whereas $\vec{H}_{v, e}^{=}$denotes a set of $\Sigma(\bar{X})=$-rewrite rules orienting non-Horn hypotheses. Furthermore, let $H_{n e}^{e q}$ denote the subset of the set $H_{n e}$ of non-executable hypotheses that are equations or conditional equations. In our intended use, $(\Sigma, E)$ will actually stand for an equational theory of the form: $\left(\Sigma(\bar{X}), E \cup B \cup H_{e} \cup H_{w u} \cup H_{n e}^{e q}\right)$, where $(\Sigma, E \cup B)$ is the original theory $\mathcal{E}$ on which we are doing inductive reasoning about theorems valid in its initial algebra $T_{\mathcal{E}}$.

Lemma 1. Let $(\Sigma, E)$ be an order-sorted equational theory, and let $\left(\Sigma^{=}, E\right)$ be the extension of $(\Sigma, E)$ where $\Sigma$ is extended to $\Sigma^{=}$as described in Section $\left[2.5^{34}\right.$ so that QF $\Sigma$-formulas are represented as terms of the new Boolean sort added to the sorts of $\Sigma$. Let $\varphi$ and $\psi$ be any two $Q F$ formulas such that $\varphi={ }_{E} \psi$. Then, these formulas are $E$-equivalent, i.e., for any $(\Sigma, E)$-algebra $A$ and any assignment $a \in[X \rightarrow A]$, where $X$ contains the variables of $\varphi$ and $\psi$, we have the equivalence:

$$
A, a \models \varphi \Leftrightarrow A, a \models \psi .
$$

That is, we have $E \models \varphi \Leftrightarrow \psi$.
Proof. Since the equality relation is reflexive and transitive, and so is logical equivalence, it is enough to prove the lemma when the equality $\varphi={ }_{E} \psi$ is obtained by a single step of $E$-equality. That is, there is position $p$ in $\varphi$ such that $\left.\varphi\right|_{p}$ is an equation $t=t^{\prime}$, and there is a term position i.q in such an equation, $1 \leqslant i \leqslant 2$, such that, taking w.l.o.g. $i=1$, there is an order-sorted substitution $\theta$ and a (possibly conditional) equation $(u=v$ if $C) \in E$ (or $(v=$ $u$ if $C) \in E$ ) such that $E \vdash C \theta$ and $\psi=\varphi[v \theta]_{p .1 . q}$. In other words, $\psi$ only differs from $\varphi$ in that at position $p$ the equation now has the form $t[v \theta]_{q}=t^{\prime}$. But, since $A=E$, we must have $t a=t[v \theta]_{q} a$, and therefore we also must have $A, a\left|=t=t^{\prime} \Leftrightarrow A, a\right|=t[v \theta]_{q}=t^{\prime}$. But, by the inductive definition of the satisfaction relation $A, a=\varphi$ in terms of the Boolean structure of $\varphi$, a simple in induction on $|p|$, the length of $p$, forces $A, a|=\varphi \Leftrightarrow A, a|=\psi$, as desired. $\square$

Lemma 2. Let $[\bar{X}, \mathcal{E}, H]$ be an inductive theory, and consider again the signature extension $\Sigma(X) \subseteq \Sigma(X)=$ allowing the representation of $Q F \Sigma(X)$-formulas as terms of the new Boolean sort added to the sorts of $\Sigma(X)$. Let $\varphi$ and $\psi$ be any two $Q F \Sigma(X)$-formulas such that $\varphi \rightarrow_{\overrightarrow{\mathcal{E}}_{\overline{\bar{X}_{U}}}^{*} \cup \vec{H}_{e_{U}}^{+}}^{*} \psi$. Then, these formulas are $[\bar{X}, \mathcal{E}, H]$-equivalent, i.e., for any $[\bar{X}, \mathcal{E}, H]-$ model $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ and any constructor ground substitution $\beta$ whose domain contains the variables of $\varphi$ and $\psi$, we have the equivalence:

$$
T_{\mathcal{E}^{\text {口 }}}=\varphi^{\circ}(\alpha \uplus \beta) \Leftrightarrow T_{\mathcal{E}^{\text { }}}=\psi^{\circ}(\alpha \uplus \beta)
$$

That is, we have $[\bar{X}, \mathcal{E}, H] \models \varphi \Leftrightarrow \psi$.

[^23]Proof．Since the rewrite relation $\rightarrow_{\overrightarrow{\mathcal{F}_{\overline{\bar{x}_{U}}}^{=}} \cup \vec{H}_{e_{U}}^{+}}^{*}$ is reflexive and transitive，and so is logical equivalence，it is enough to prove the lemma for a single rewrite step $\varphi \rightarrow \vec{\varepsilon}_{\bar{X}_{U}} \cup \vec{H}_{e_{U}}^{+} \psi$ ． We give separate proofs of the lemma for the three possible cases in which a rewrite $\varphi \rightarrow \vec{\varepsilon}_{\overline{\bar{X}}_{U}} \cup \vec{H}_{e_{U}}^{+} \psi$ can happen．

Case（1）．The rewrite is performed with a rule in $\overrightarrow{\mathcal{E}}_{U} \cup \vec{H}_{e_{U}} \cup \vec{H}_{w u_{U}}$ ．Then the result fol－ lows from $[\bar{X}, \mathcal{E}, H] \vDash E \cup B \cup H_{e} \cup H_{w u}$ and Lemma 1 applied to the equational theory $\left(\Sigma(\bar{X}), E \cup B \cup H_{e} \cup H_{w u}\right)$ ．This finishes the proof for Case（1）．

Case（2）．The rewrite is the the application of a rule in $\overrightarrow{\mathcal{E}}_{\bar{X}_{U}}$ not in $\overrightarrow{\mathcal{E}}_{U}$ ；or（3）it is the ap－ plication of a rule in $\vec{H}_{\mathrm{v}, e}^{=}$．In case（2），all such rules are of the form $(u=v) \rightarrow \phi$ if $C$ with $\phi$ a $\Sigma$－formula．For example，if［，，］is a pairing constructor in $\Sigma$ satisfying no axioms， then there is a rule in $\overrightarrow{\mathcal{E}}_{\bar{X}_{U}}$ of the form $\left([x, y]=\left[x^{\prime}=y^{\prime}\right]\right) \rightarrow x=x^{\prime} \wedge y=y^{\prime}$ ．Therefore， $\varphi \rightarrow \vec{\varepsilon}_{\overrightarrow{\bar{X}}_{U}} \psi$ exactly means that there is position $p$ in $\varphi$ such that $\left.\varphi\right|_{p}$ is an equation $t=t^{\prime}$, and there is an order－sorted substitution $\theta$ and a rule $(u=v) \rightarrow \phi$ if $C$ in $\overrightarrow{\mathcal{E}}_{\bar{X}_{U}}^{=}$such that：（a） $(u=v) \theta={ }_{B_{0}}\left(t=t^{\prime}\right)$ ，（b） $\mathcal{E}_{\bar{X}_{U}}^{=} \vdash C \theta$ ，and（c）$\psi=\varphi[\phi \theta]_{p}$ ．We now have to prove that for any any $[\bar{X}, \mathcal{E}, H]$－model $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ and any constructor ground substitution $\beta$ whose domain contains the variables of $\varphi$ and $\varphi[\phi \theta]_{p}$ ，we have the equivalence：

$$
T_{\mathcal{E}^{\square}}=\varphi^{\circ}(\alpha \uplus \beta) \Leftrightarrow T_{\mathcal{E}^{\text {® }}}=\varphi[\phi \theta]_{p}^{\circ}(\alpha \uplus \beta) .
$$

But note that if we have a rewrite $\varphi \rightarrow \overrightarrow{\mathcal{E}}_{\overline{\bar{X}}_{U}} \varphi[\phi \theta]_{p}$ with substitution $\theta$ ，we also have a rewrite $\varphi^{\circ} \rightarrow \overrightarrow{\mathcal{E}}_{U}^{\overline{\bar{U}}} \boldsymbol{\varphi}[\phi \theta]_{p}^{\circ}$ with substitution $\theta^{\circ}$ ，so that $\varphi[\phi \theta]_{p}^{\circ}=\varphi^{\circ}\left[\phi \theta^{\circ}\right]_{p}$ ．But a simple induction on $|p|$ using the inductive definition of the satisfaction relation $T_{\mathcal{E}^{\square}} \models \varphi^{\circ}$ in terms of the Boolean structure of $\varphi$ ，together with the fact that for this rewrite at po－ sition $p$ to happen $\left.\varphi\right|_{p} \equiv t=t^{\prime}$ must be a $\Sigma(X)$－equation，forcing $T_{\mathcal{E}^{\mathrm{a}}} \vDash\left(t=t^{\prime}\right)^{\circ}$ iff $T_{\mathcal{E}} \models\left(t=t^{\prime}\right)^{\circ}$ iff（by the properties of $\mathcal{E}_{U}^{=}$）$T_{\mathcal{E}} \models \phi \theta^{\circ}$ iff $T_{\mathcal{E}^{\text {口 }}}=\phi \theta^{\circ}$ ，gives us $T_{\mathcal{E}^{\square}}=\varphi^{\circ}(\alpha \uplus \beta) \Leftrightarrow T_{\mathcal{E}^{\square}}=\varphi[\phi \theta]_{p}^{\circ}(\alpha \uplus \beta)$ ，as desired．This finishes the proof of Case（2）．
Case（3）．There is a non－Horn clause $\Upsilon \rightarrow \Delta$ in $H_{e}^{=}$，oriented as a rewrite rule $\Upsilon \rightarrow(\Delta \rightarrow$ $\top$ ），a position $p$ in $\varphi$ ，and a substitution $\theta$ such that：（i）$\left.\varphi\right|_{p}={ }_{B_{0}}=\Delta \theta$（where $B_{0}^{=}$are the ax－ ioms in $\overrightarrow{\mathcal{E}}_{\bar{X}_{U}}^{=}$）and（ii）$T \in \Upsilon \alpha!{\overrightarrow{\mathcal{E}_{\overline{\bar{X}_{U}}}} \cup_{\vec{H}_{e_{U}}} \text { ．But using the（reflexive transitive closure of）the }}^{\text {a }}$ already proved cases（1）－（2）above，$\top \in \Upsilon \theta!_{\overrightarrow{\bar{X}}_{\overline{\bar{X}_{U}}} \cup \vec{H}_{e_{U}}}$ implies that for any $[\bar{X}, \mathcal{E}, H]$－model （ $T_{\mathcal{E}^{\square}},[\bar{\alpha}]$ ）and any constructor ground substitution $\beta$ whose domain contains the variables of $\varphi$ and $\psi$ ，we have the equivalence：

$$
T_{\mathcal{E}^{\mathrm{a}}}=(\Upsilon \theta)^{\circ}(\alpha \uplus \beta) \Leftrightarrow T_{\mathcal{E}^{\mathrm{a}}}=\mathrm{\top}(\alpha \uplus \beta)
$$

that is，we have $T_{\mathcal{E}^{\text { }}}=(\Upsilon \theta)^{\circ}(\alpha \uplus \beta)$ But we also have $[\bar{X}, \mathcal{E}, H] \models(\Upsilon \rightarrow \Delta) \theta$ ，which forces $T_{\mathcal{E}^{\text {口 }}}=(\Delta \theta)^{\circ}(\alpha \uplus \beta)$ ，and therefore the equivalence

$$
T_{\mathcal{E}^{\text {口 }}}=(\Delta \theta)^{\circ}(\alpha \uplus \beta) \Leftrightarrow T_{\mathcal{E}^{\text { }}}=\top(\alpha \uplus \beta)
$$

which by the Tarskian semantics for QF formulas forces the equivalence

$$
T_{\mathcal{E}^{\text { }}}=\left(\varphi[\Delta \theta]_{p}\right)^{\circ}(\alpha \uplus \beta) \Leftrightarrow T_{\mathcal{E}^{\text { }}}=\left(\varphi[\top]_{p}\right)^{\circ}(\alpha \uplus \beta)
$$

as desired．This finishes the proof of Case（3），and therefore that of the Lemma．$\square$

Call two inductive theories $[\bar{X}, \mathcal{E}, H]$ and $\left[\bar{X}, \mathcal{E}, H^{\prime}\right]$ semantically equivalent, denoted $[\bar{X}, \mathcal{E}, H] \equiv[\bar{X}, \mathcal{E}, H]$, iff they have the same models. The following Lemma gives a useful sufficient condition for semantic equivalence.

Lemma 3. Let $[\bar{X}, \mathcal{E}, H]$ be an inductive theory, and $\bar{G}, \overline{G^{\prime}}$ be two conjunctions of ground $\Sigma(\bar{X})$-equations. Then, $[\bar{X}, \mathcal{E}, H] \models \bar{G} \Leftrightarrow \overline{G^{\prime}}$ implies $[\bar{X}, \mathcal{E}, H \cup\{\bar{G}\}] \equiv\left[\bar{X}, \mathcal{E}, H \cup\left\{\overline{G^{\prime}}\right\}\right]$.

Proof. We prove the $(\Rightarrow)$ implication of the semantic equivalence $\equiv$. The $(\Leftarrow)$ implication is entirely symmetric, changing the roles of $\bar{G}$ and $\overline{G^{\prime}}$. For any model $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ of $[\bar{X}, \mathcal{E}, H \cup\{\bar{G}\}]$ we of course have $\left(T_{\mathcal{E}^{\bullet}},[\bar{\alpha}]\right) \models \bar{G}$. But then, $[\bar{X}, \mathcal{E}, H] \models \bar{G} \Leftrightarrow \overline{G^{\prime}}$ forces $\left(T_{\mathcal{E}^{\circ}},[\bar{\alpha}]\right) \models \overline{G^{\prime}}$, which in turn forces $\left(T_{\mathcal{E}^{\circ}},[\bar{\alpha}]\right)$ to be a model of $\left[\bar{X}, \mathcal{E}, H \cup\left\{\overline{G^{\prime}}\right\}\right]$, as desired.

We now resume our proof of the Soundness Theorem. The cases are as follows:
EPS. By assumption we have $[\bar{X}, \mathcal{E}, H] \not \models \Gamma \rightarrow \Lambda$, but $[\bar{X}, \mathcal{E}, H] \models(\Gamma \rightarrow \Lambda)!{\overrightarrow{\mathcal{E}_{\overline{X_{U}}}} \cup \vec{H}_{e_{U}^{+}}^{+}}$. But by Lemma[2]we must have $[\bar{X}, \mathcal{E}, H] \models \Gamma \rightarrow \Lambda$ iff $[\bar{X}, \mathcal{E}, H] \models(\Gamma \rightarrow \Lambda)!_{\overrightarrow{\bar{E}}_{\bar{U}}} \cup{\overrightarrow{\mathcal{H}_{e U}^{+}}}^{\text {, }}$, contradicting our original assumption.

CVUL. By the minimality assumption we have: (i) $[\bar{X}, \mathcal{E}, H] \not \models \Gamma, \Gamma^{\prime} \rightarrow \Lambda$, where the $\Gamma^{\prime}$ are $\mathcal{E}_{1}$-equalities; and (ii) $\left\{\left[\bar{X}_{\uplus} \uplus \bar{Y}_{\alpha}, \mathcal{E},\left(\left.H \cup \tilde{\bar{\alpha}}\right|_{\bar{X}_{r}}\right)_{\text {simp }}\right] \models\left(\Gamma^{\prime} \rightarrow \Lambda\right) \bar{\alpha}\right\}_{\alpha \in U n i f \delta_{1}\left(\Gamma^{\circ}\right)}$. But (i) exactly means that there is a ground constructor substitution $\gamma$ with domain $X$ such that $\left(T_{\mathcal{E}^{\bullet}},[\bar{\gamma}]\right)$ is a model of $[\bar{X}, \mathcal{E}, H]$, which implies (a) $\left(T_{\mathcal{E}^{\square}},[\bar{\gamma}]\right)=H$; and that for $Z=$ $\operatorname{vars}\left(\Gamma, \Gamma^{\prime} \rightarrow \Lambda\right)$ there is a ground constructor substitution $\beta$ with domain $Z$ disjoint from $X$ such that (b) $T_{\mathcal{E}^{\square}} \mid=\left(\Gamma, \Gamma^{\prime} \rightarrow \Lambda\right)^{\circ}(\gamma \uplus \beta)$, which means that (b). $1 T_{\mathcal{E}^{\square}}=\left(\Gamma^{\prime}, \Gamma^{\prime \prime}\right)^{\circ}(\gamma \uplus \beta)$, and (b). $2 T_{\mathcal{E}^{\square}} \not \models \Lambda^{\circ}(\gamma \uplus \beta)$. Let $X_{\Gamma} \uplus Z_{\Gamma}=\operatorname{vars}\left(\Gamma^{\circ}\right)$, with $X_{\Gamma} \subseteq X$, and $Z_{\Gamma} \subseteq Z$. But (b). 1 implies that $\left.(\gamma \uplus \beta)\right|_{X_{\Gamma} \uplus Z_{\Gamma}}$ is a ground constructor unifier of $\Gamma^{\circ}$. Therefore, there is an idempotent variant constructor $\mathcal{E}_{1}$-unifier $\alpha$ of $\Gamma^{\circ}$ with domain $X_{\Gamma} \uplus Z_{\Gamma}$ and fresh range $Y$ (so that $Y \supseteq Y_{\alpha}$ ), and a ground constructor substitution $\tau$ with domain $Y$ such that $\left.(\gamma \uplus \beta)\right|_{X_{r} \uplus Z_{r}}={ }_{B_{1}} \alpha \tau$. This means that $\left(T_{\mathcal{E}^{\mathrm{B}}},\left[\left.\bar{\gamma} \uplus \bar{\tau}\right|_{Y_{\alpha}}\right]\right)$ is a model of the inductive theory

$$
\left[\bar{X}_{\uplus} \bar{Y}_{\alpha}, \mathcal{E},\left(H \cup \tilde{\bar{\alpha}}_{\bar{X}_{r}}\right)_{\text {simp }}\right]
$$

since: (i) $\left(T_{\mathcal{E}^{\square}},\left[\left.\bar{\gamma} \uplus \bar{\tau}\right|_{Y_{\alpha}}\right]\right) \models H$ because $\left(T_{\mathcal{E}^{\mathrm{B}}},[\bar{\gamma}]\right) \models H$ (the variables $Y_{\alpha}$ are fresh and therefore do not appear in $H$ ); and (ii) $\left.\left(T_{\mathcal{E}^{\bullet}},\left[\left.\bar{\gamma} \uplus \bar{\tau}\right|_{Y_{\alpha}}\right]\right) \models \tilde{\bar{\alpha}}\right|_{\bar{X}_{r}}$, since for each $\bar{x} \in \bar{X}$ we have $\left.\left(\left.\gamma \uplus \tau\right|_{Y_{\alpha}}\right)(x)=\gamma(x)=(\gamma \uplus \beta) \mid X_{T_{\uplus} \uplus Z_{r}}\right)(x)=B_{B_{1}}(\alpha \tau)(x)=\left.\alpha(x) \tau\right|_{Y_{\alpha}}=$ $\alpha(x)\left(\left.\gamma \uplus \tau\right|_{Y_{\alpha}}\right)$. Therefore, by (ii) we have $\left(T_{\mathcal{E}^{\mathrm{B}}},\left[\left.\bar{\gamma} \uplus \bar{\tau}\right|_{Y_{\alpha}}\right]\right) \mid=\left(\Gamma^{\prime} \rightarrow \Lambda\right) \bar{\alpha}$. But since $\operatorname{vars}\left(\left(\Gamma^{\prime} \rightarrow \Lambda\right) \bar{\alpha}\right)=Z \backslash Z_{\Gamma} \uplus Y \backslash Y_{\alpha}$, in particular, for the ground constructor substitution $\left.\left.\beta\right|_{Z \backslash Z_{r}} \uplus \tau\right|_{Y Y_{\alpha}}$ we must have $T_{\mathcal{E}^{\square}}=\left(\Gamma^{\prime} \rightarrow \Lambda\right)^{\circ} \alpha\left(\left.\left.\left.\gamma \uplus \tau\right|_{Y_{\alpha}} \uplus \beta\right|_{Z \backslash Z_{r}} \uplus \tau\right|_{Y Y_{Y_{\alpha}}}\right)$, that is, $T_{\mathcal{E}^{\square}} \models\left(\Gamma^{\prime} \rightarrow \Lambda\right)^{\circ} \alpha\left(\left.\gamma \uplus \tau \uplus \beta\right|_{Z \backslash Z_{r}}\right)$. But since $\left.(\gamma \uplus \beta)\right|_{X_{r} \uplus Z_{r}}={ }_{B_{1}} \alpha \tau$, this forces $T_{\mathcal{E}^{\square}}=$ $\left(\Gamma^{\prime} \rightarrow \Lambda\right)^{\circ}(\gamma \uplus \beta)$, which by (b). 1 forces $T_{\mathcal{E}^{\square}} \models \Lambda^{\circ}(\gamma \uplus \beta)$, contradicting (b).2, as desired.

CVUFR. By the minimality assumption we have (i). $1[\bar{X}, \mathcal{E}, H] \not \models \Gamma \rightarrow \Lambda \wedge(u=v, \Delta)$, (i). $2 \operatorname{Unif}_{\mathcal{E}_{1}}^{Q}\left((u=v)^{\circ}\right)=\varnothing$, and (ii) $[\bar{X}, \mathcal{E}, H] \models \Gamma \rightarrow \Lambda \wedge \Delta$. But (i). 1 means that, for $Y=\operatorname{vars}(\Gamma \rightarrow \Lambda \wedge(u=v, \Delta))$, we have constructor ground substitutions $\alpha$ and $\beta$ with respective domains $X$ and $Y$ such that: (a) $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ is a model of $[\bar{X}, \mathcal{E}, H]$, and (b) $T_{\mathcal{E}^{\mathrm{a}}} \not \models(\Gamma \rightarrow \Lambda \wedge(u=v, \Delta))^{\circ}(\alpha \uplus \beta)$. That is, (b). $1 T_{\mathcal{E}^{\mathrm{a}}} \models \Gamma^{\circ}(\alpha \uplus \beta)$, and (b). 2 $T_{\mathcal{E}^{\square}} \mid \neq(\Lambda \wedge(u=v, \Delta))^{\circ}(\alpha \uplus \beta)$. But (b). 2 is equivalent to: $T_{\mathcal{E}^{\square}} \vDash \neg(\Lambda)^{\circ}(\alpha \uplus \beta)$ or $\left(T_{\mathcal{E}^{\square}} \models\right.$
$(u \neq v)^{\circ}(\alpha \uplus \beta)$ and $\left.T_{\mathcal{E}^{\square}}=(\neg \Delta)^{\circ}(\alpha \uplus \beta)\right)$. And (i). 2 means that $T_{\mathcal{E}^{\square}}=(u \neq v)^{\circ}(\alpha \uplus \beta)$ is necessarily true. Therefore, (b). 2 is equivalent to: $T_{\mathcal{C}^{\square}} \not \models(\Lambda \wedge \Delta)^{\circ}(\alpha \uplus \beta)$, which, together with (b). 1 and (a), contradicts (ii), as desired.

SUBL. We prove soundness for the two different cases of the rule.
Case $x$ is a variable. By the minimality assumption we have (i) $[\bar{X}, \mathcal{E}, H] \not \models x=u, \Gamma \rightarrow \Lambda$ with with $x$ a variable of sort $s, l s(u) \leqslant s$, and $x$ not appearing in $u$, and (ii) $[\bar{X}, \mathcal{E}, H] \models$ $(\Gamma \rightarrow \Lambda)\{x \mapsto u\}$. But (i) means that, for $Y=\operatorname{vars}(x=u, \Gamma \rightarrow \Lambda)$, we have constructor ground substitutions $\alpha$ and $\beta$ with respective domains $X$ and $Y$ such that: (a) $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ is a model of $[\bar{X}, \mathcal{E}, H]$, and (b) $T_{\mathcal{E}^{\square}} \not \models(x=u, \Gamma \rightarrow \Lambda)^{\circ}(\alpha \uplus \beta)$. That is, (b). $1 T_{\mathcal{E}^{\square}} \vDash(x=u, \Gamma)^{\circ}(\alpha \uplus \beta)$, and (b). $2 T_{\mathcal{E}^{\square}} \not \models \Lambda^{\circ}(\alpha \uplus \beta)$. But (b). 1 and $x$ not appearing in $u$ imply that $\beta(x)=\varepsilon u^{\circ}\left(\left.\alpha \uplus \beta\right|_{Y \backslash\{x\}}\right)$. Therefore, $(\alpha \uplus \beta)=\varepsilon(\alpha \uplus\{x \mapsto$ $\left.\left.u^{\circ}\left(\left.\alpha \uplus \beta\right|_{Y \backslash\{x\}}\right)\right\}\left.\uplus \beta\right|_{Y \backslash\{x\}}\right)$. But (ii) and (a) imply that $T_{\mathcal{E}^{\square}} \models \Gamma^{\circ}\left\{x \mapsto u^{\circ}\right\}\left(\left.\alpha \uplus \beta\right|_{Y \backslash\{x\}}\right)$, that is, $T_{\mathcal{E}^{\text { }}}=\Gamma^{\circ}\left(\left.\alpha \uplus\left\{x \mapsto u^{\circ}\left(\left.\alpha \uplus \beta\right|_{Y \backslash\{x\}}\right)\right\} \uplus \beta\right|_{Y \backslash\{x\}}\right)$, which by the semantic equivalence $(\alpha \uplus \beta)=\varepsilon \in\left(\left.\alpha \uplus\left\{x \mapsto u^{\circ}\left(\left.\alpha \uplus \beta\right|_{Y \backslash\{x\}}\right)\right\} \uplus \beta\right|_{Y \backslash\{x\}}\right)$ contradicts (b), as desired.

Case $\bar{x} \in \bar{X}$. By the minimality assumption we have (i) $[\bar{X}, \mathcal{E}, H] \not \models \bar{x}=u, \Gamma \rightarrow \Lambda$, with $\bar{x}$ a fresh constant of sort $s, l s(u) \leqslant s$, and $\bar{x}$ not appearing in $u$, and (ii) $\left[\bar{X} \uplus \bar{Y}_{u}, \mathcal{E},(H \cup\{\bar{x}=\right.$ $\left.\bar{u}\})_{\operatorname{simp}}\right] \equiv(\Gamma \rightarrow \Lambda)\left(\{y \mapsto \bar{y}\}_{y \in Y_{u}} \uplus\{\bar{x} \mapsto \bar{u}\}\right)$. But (i) means that, for $Y=\operatorname{vars}(\bar{x}=u, \Gamma \rightarrow$ $\Lambda$ ), we have constructor ground substitutions $\alpha$ and $\beta$ with respective domains $X$ and $Y$ such that: (a) $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ is a model of $[\bar{X}, \mathcal{E}, H]$, and (b) $T_{\mathcal{E}^{\square}} \not \models(\bar{x}=u, \Gamma \rightarrow \Lambda)^{\circ}(\alpha \uplus \beta)$. That is, (b). $1 T_{\mathcal{E}^{\square}}=(\bar{x}=u, \Gamma)^{\circ}(\alpha \uplus \beta)$, and (b). $2 T_{\mathcal{E}^{\text {a }}} \not \models \Lambda^{\circ}(\alpha \uplus \beta)$. But (b). 1 and $\bar{x}$ not appearing in $u$ imply that $\alpha(x)=\mathcal{\varepsilon} u^{\circ}\left(\left.\left.\alpha\right|_{X \backslash\{x\}} \uplus \beta\right|_{Y_{u}}\right)$. Therefore, $(\alpha \uplus \beta)=\mathcal{E}\left(\left.\alpha\right|_{X \backslash\{x\}} \uplus\{x \mapsto\right.$ $\left.\left.u^{\circ}\left(\left.\left.\alpha\right|_{X \backslash\{x\}} \uplus \beta\right|_{Y_{u}}\right)\right\} \uplus \beta\right)$. Now note that $\operatorname{vars}\left((\Gamma \rightarrow \Lambda)\left(\{y \mapsto \bar{y}\}_{y \in Y_{u}} \uplus\{\bar{x} \mapsto \bar{u}\}\right)\right)=Y \backslash Y_{u}$, and that $\left(T_{\mathcal{E}^{\square}},\left[\left.\bar{\alpha} \uplus \bar{\beta}\right|_{Y_{u}}\right]\right)$ is a model of $\left[\bar{X} \uplus \bar{Y}_{u}, \mathcal{E},(H \cup\{\bar{x}=\bar{u}\})_{\text {simp }}\right]$, because it satisfies $H$ since $\left(T_{\mathcal{E}^{\bullet}},[\bar{\alpha}]\right)$ does, and it satisfies $\bar{x}=\bar{u}$ by $\alpha(x)=\mathcal{E}_{\mathcal{E}} u^{\circ}\left(\left.\left.\alpha\right|_{X \backslash\{x\}} \uplus \beta\right|_{Y_{u}}\right)$. Therefore, $\left(T_{\mathcal{E}^{\square}},\left[\left.\bar{\alpha} \uplus \bar{\beta}\right|_{Y_{u}}\right]\right),\left[\left.\beta\right|_{Y \backslash Y_{u}}\right] \models(\Gamma \rightarrow \Lambda)\left(\{y \mapsto \bar{y}\}_{y \in Y_{u}} \uplus\{\bar{x} \mapsto \bar{u}\}\right)$, that is, $T_{\mathcal{C}^{\square}} \models((\Gamma \rightarrow$ $\left.\Lambda)\left(\{y \mapsto \bar{y}\}_{y \in Y_{u}} \uplus\{\bar{x} \mapsto \bar{u}\}\right)\right)^{\circ}(\alpha \uplus \beta)$, which means, $T_{\mathcal{E}^{\square}}=(\Gamma \rightarrow \Lambda)^{\circ}\left\{x \mapsto u^{\circ}\right\}(\alpha \uplus \beta)$, which by the semantic equivalence $(\alpha \uplus \beta)=_{\mathcal{E}}\left(\left.\alpha\right|_{X \backslash\{x\}} \uplus\left\{x \mapsto u^{\circ}\left(\left.\left.\alpha\right|_{X \backslash\{x\}} \uplus \beta\right|_{Y_{u}}\right)\right\} \uplus \beta\right)$ forces $T_{\mathcal{E}^{\square}}=\left((\Gamma \rightarrow \Lambda)^{\circ}(\alpha \uplus \beta)\right.$, which by (b). 1 forces $T_{\mathcal{E}^{\square}} \models \Lambda^{\circ}(\alpha \uplus \beta)$, contradicting (b). 2 , as desired.

SUBR. We prove soundness for the somewhat more involved case $\bar{x} \in \bar{X}$ and leave the simper and similar case when $x$ is a variable for the reader.
Case $\bar{x} \in \bar{X}$. By the minimality assumption we have: (i) $[\bar{X}, \mathcal{E}, H] \not \models \Gamma \rightarrow \Lambda \wedge \bar{x}=u$, where $\Lambda \neq \top, \bar{x}$ has sort $s, l s(u) \leqslant s$, and $\bar{x}$ does not appear in $u$; (ii). $1[\bar{X}, \mathcal{E}, H] \models \Gamma \rightarrow \bar{x}=u$; and (ii). $2\left[\bar{X} \uplus \bar{Y}_{u}, \mathcal{E},(H \cup\{\bar{x}=\bar{u}\})_{\text {simp }}\right] \equiv(\Gamma \rightarrow \Lambda)\left(\{y \mapsto \bar{y}\}_{y \in Y_{u}} \uplus\{\bar{x} \mapsto \bar{u}\}\right)$. But (i) means that, for $Y=\operatorname{vars}(\Gamma \rightarrow \Lambda \wedge \bar{x}=u)$, we have constructor ground substitutions $\alpha$ and $\beta$ with respective domains $X$ and $Y$ such that: (a) $\left(T_{\mathcal{C}^{\square}},[\bar{\alpha}]\right)$ is a model of $[\bar{X}, \mathcal{E}, H]$, and (b) $T_{\mathcal{E}^{\square}} \not \models(\Gamma \rightarrow \Lambda \wedge \bar{x}=u)^{\circ}(\alpha \uplus \beta)$. That is, (b). $1 T_{\mathcal{E}^{\square}} \models(\Gamma)^{\circ}(\alpha \uplus \beta)$, and (b). $2 T_{\mathcal{E}^{\square}} \not \models\left(\Lambda^{\circ} \wedge x=u^{\circ}\right)(\alpha \uplus \beta)$, which is equivalent to $\left(T_{\mathcal{E}^{\square}} \not \models \Lambda^{\circ}(\alpha \uplus \beta)\right.$ or $T_{\mathcal{E}^{\square}} \not \models x=u^{\circ}(\alpha \uplus \beta)$ ). But (b). 1 and (ii). 1 force $T_{\mathcal{E}^{\square}} \models x=u^{\circ}(\alpha \uplus \beta)$, making (b). 2 equivalent to (b). $2^{\prime} T_{\mathcal{E}^{\square}} \not \models \Lambda^{\circ}(\alpha \uplus \beta)$. And $\bar{x}$ not appearing in $u$ imply that $\alpha(x)=\mathcal{E}^{\prime}$ $u^{\circ}\left(\left.\left.\alpha\right|_{X \backslash\{x\}} \uplus \beta\right|_{Y_{u}}\right)$. Therefore, $(\alpha \uplus \beta)=\varepsilon\left(\left.\alpha\right|_{X \backslash\{x\}} \uplus\left\{x \mapsto u^{\circ}\left(\left.\left.\alpha\right|_{X \backslash\{x\}} \uplus \beta\right|_{Y_{u}}\right)\right\} \uplus \beta\right)$. Now note that $\operatorname{vars}\left((\Gamma \rightarrow \Lambda)\left(\{y \mapsto \bar{y}\}_{y \in Y_{u}} \uplus\{\bar{x} \mapsto \bar{u}\}\right)\right)=Y \backslash Y_{u}$, and that $\left(T_{\mathcal{E}^{\square}},\left[\left.\bar{\alpha} \uplus \bar{\beta}\right|_{Y_{u}}\right]\right)$ is a model of $\left[\bar{X}_{\uplus} \bar{Y}_{u}, \mathcal{E},(H \cup\{\bar{x}=\bar{u}\})_{\text {simp }}\right]$, because it satisfies $H$ since $\left(T_{\mathcal{E}^{\bullet}},[\bar{\alpha}]\right)$ does, and it
satisfies $\bar{x}=\bar{u}$ by $\alpha(x)=\mathcal{E} u^{\circ}\left(\left.\left.\alpha\right|_{X \backslash\{x\}} \uplus \beta\right|_{Y_{u}}\right)$ ．Therefore，$\left(T_{\mathcal{E}^{\square}},\left[\left.\bar{\alpha} \uplus \bar{\beta}\right|_{Y_{u}}\right]\right),\left[\left.\beta\right|_{Y \backslash Y_{u}}\right]=(\Gamma \rightarrow$ $\Lambda)\left(\{y \mapsto \bar{y}\}_{y \in Y_{u}} \uplus\{\bar{x} \mapsto \bar{u}\}\right)$ ，that is，$T_{\mathcal{E}^{\square}} \models\left((\Gamma \rightarrow \Lambda)\left(\{y \mapsto \bar{y}\}_{y \in Y_{u}} \uplus\{\bar{x} \mapsto \bar{u}\}\right)\right)^{\circ}(\alpha \uplus \beta)$ ， which means，$T_{\mathcal{E}^{\square}}=(\Gamma \rightarrow \Lambda)^{\circ}\left\{x \mapsto u^{\circ}\right\}(\alpha \uplus \beta)$ ，which by the semantic equivalence $(\alpha \uplus \beta)=\varepsilon_{\mathcal{E}}\left(\left.\alpha\right|_{X \backslash\{x\}} \uplus\left\{x \mapsto u^{\circ}\left(\left.\left.\alpha\right|_{X \backslash\{x\}} \uplus \beta\right|_{Y_{u}}\right)\right\} \uplus \beta\right)$ forces $T_{\mathcal{E}^{\square}}=\left((\Gamma \rightarrow \Lambda)^{\circ}(\alpha \uplus \beta)\right.$ ， which by（b）． 1 forces $T_{\mathcal{E}^{\square}}=\Lambda^{\circ}(\alpha \uplus \beta)$ ，contradicting（b）． $2^{\prime}$ ，as desired．

NS．We prove soundness for the fully general version of the NS rule．By the minimal－ ity assumption we have：（i）$[\bar{X}, \mathcal{E}, H] \not \models(\Gamma \rightarrow \Lambda)[f(\vec{v})]_{p}$ ；and（ii）$\left\{\left[\bar{X} \uplus \bar{Y}_{i, j}, \mathcal{E}, H \uplus\right.\right.$ $\left.\left.\left.\tilde{\bar{\alpha}}_{i, j}\right|_{\bar{X}_{f(\vec{r})}}\right] \models\left(\Gamma_{i},(\Gamma \rightarrow \Lambda)\left[r_{i}\right]_{p}\right) \bar{\alpha}_{i, j}\right\}_{i \in I_{0}}^{j \in J_{i}}$ ．But（i）exactly means that there is a model $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ of $[\bar{X}, \mathcal{E}, H]$ such that $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right) \not \models(\Gamma \rightarrow \Lambda)[f(\vec{v})]_{p}$ ．Therefore，there is a ground constructor substitution $\beta$ with domain the variables $Z$ of $\Gamma \rightarrow \Lambda$ such that $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right),[\beta] \not \models(\Gamma \rightarrow \Lambda)[f(\vec{v})]_{p}$ ，that is，（a）$T_{\mathcal{E}^{\square}} \not \models(\Gamma \rightarrow \Lambda)^{\circ}\left[f(\vec{v})^{\circ}\right]_{p}(\alpha \uplus \beta)$ ．But，by suf－ ficient completeness of $f$ ，this means that there exist $i \in I_{0}, \alpha_{i, j} \in \operatorname{Unif}_{B_{0}}\left(f(\vec{v})^{\circ}=f\left(\overrightarrow{u_{i}}\right)\right)$ ， with $\operatorname{ran}\left(\alpha_{i, j}\right)$ fresh variables，and $\rho \in\left[\operatorname{ran}\left(\alpha_{i, j}\right) \rightarrow T_{\Omega}\right]$ such that，denoting $Z_{f(\vec{v})}=$ $\operatorname{vars}(f(\vec{v}))$ ，（b．1）$\left.f(\vec{v})^{\circ}(\alpha \uplus \beta)\right|_{X_{f(\vec{v})} \uplus Z_{f(\vec{v})}}={ }_{B_{0}} f\left(\overrightarrow{u_{i}}\right) \alpha_{i, j} \rho$ ；which forces（b．2）$(\alpha \uplus \beta)={ }_{B_{0}}$ $\left.\left.\alpha\right|_{X \backslash X_{f(\vec{r})}} \uplus \alpha_{i, j} \rho \uplus \beta\right|_{Z \backslash Z_{f(\vec{r})}}$ ；and we furthermore have（b．3）$T_{\mathcal{E}^{\square}} \models \Gamma_{i} \alpha_{i, j} \rho$ ．We claim that $\left(T_{\mathcal{E}^{\square}},\left[\left.\bar{\alpha} \uplus \bar{\rho}\right|_{Y_{i, j}}\right]\right)$ is a model of $\left[\bar{X} \uplus \bar{Y}_{i, j}, \mathcal{E},\left.H \uplus \tilde{\bar{\alpha}}_{i, j}\right|_{\bar{X}_{f(\bar{v}}}\right]$ ．Showing this boils down to showing $T_{\mathcal{E}^{\square}}=x=\alpha_{i, j}(x)\left(\left.\alpha \uplus \rho\right|_{Y_{i, j}}\right), x \in X_{f(\vec{v})}$ ，which follows from（b．2）and $T_{\mathcal{E}^{\text {口 }}} \mid=B_{0}$ ． Therefore，by（ii）we have，$T_{\mathcal{E}^{\text {口 }}}=\left(\Gamma_{i},(\Gamma \rightarrow \Lambda)\left[r_{i}\right]_{p}\right)^{\circ} \alpha_{i, j}\left(\left.\alpha \uplus \rho\right|_{Y_{i, j}}\right)$ ，which forces $T_{\mathcal{E}^{\text {口 }}}=$ $\left(\Gamma_{i},(\Gamma \rightarrow \Lambda)\left[r_{i}\right]_{p}\right)^{\circ} \alpha_{i, j}\left(\left.\alpha \uplus \rho \uplus \beta\right|_{Z \backslash Z_{f(\hat{v})}}\right)$ ，which by the freshness assumption on $\operatorname{ran}\left(\alpha_{i, j}\right)$ is just $T_{\mathcal{E}^{\square}}=\left(\Gamma_{i},(\Gamma \rightarrow \Lambda)\left[r_{i}\right]_{p}\right)^{\circ}\left(\left.\left.\alpha\right|_{X \backslash X_{f(\vec{j})}} \uplus \alpha_{i, j} \rho \uplus \beta\right|_{Z \backslash Z_{f(\hat{v})}}\right)$ ，which by，（b．1），（b．3）and $T_{\mathcal{E}^{\square}}$ satisfying equation $[i]$ and $B_{0}$ ，forces $T_{\mathcal{E}^{\square}} \models(\Gamma \rightarrow \Lambda)^{\circ}\left(\left.\left.\alpha\right|_{X \backslash X_{f(\overrightarrow{)}}} \uplus \rho \alpha_{i, j} \uplus \beta\right|_{Z \backslash Z_{f(\vec{v})}}\right)$ ， which by（b．2）forces $T_{\mathcal{E}^{\square}}=(\Gamma \rightarrow \Lambda)^{\circ} \alpha_{i, j}(\alpha \uplus \beta)$ ，contradicting（a），as desired．

CS．By the minimality assumption we have（i）$[\bar{X}, \mathcal{E}, H \cup\{\Gamma \rightarrow \Delta\}] \not \vDash \Gamma \theta, \Gamma^{\prime} \rightarrow$ $\Lambda \wedge\left(\Delta \theta, \Delta^{\prime}\right)$ ；and（ii）$[\bar{X}, \mathcal{E}, H \cup\{\Gamma \rightarrow \Delta\}] \models \Gamma \theta, \Gamma^{\prime} \rightarrow \Lambda$ ．Therefore，there is a model $\left(T_{\mathcal{E}^{\bullet}},[\bar{\alpha}]\right)$ of $[\bar{X}, \mathcal{E}, H \cup\{\Gamma \rightarrow \Delta\}]$ and a constructor ground substitution $\beta$ with domain $Y=\operatorname{vars}\left(\Gamma \theta, \Gamma^{\prime} \rightarrow \Lambda \wedge\left(\Delta \theta, \Delta^{\prime}\right)\right)$ such that：（a）． $1\left(T_{\mathcal{E}^{\mathrm{a}}},[\bar{\alpha}]\right) \models \Gamma \rightarrow \Delta$ ；（a）． $2 T_{\mathcal{E}^{\mathrm{a}}} \models$ $\left(\Gamma \theta, \Gamma^{\prime}\right)^{\circ}(\alpha \uplus \beta)$ ；and（b）$T_{\mathcal{E}^{\square}} \not \models\left(\Lambda \wedge\left(\Delta \theta, \Delta^{\prime}\right)\right)^{\circ}(\alpha \uplus \beta)$ ，i．e．，either（b）． $1 T_{\mathcal{E}^{\square}} \not \models \Lambda^{\circ}(\alpha \uplus \beta)$ holds，or（b）． $2 T_{\mathcal{E}^{\text {口 }}} \neq\left(\Delta \theta, \Delta^{\prime}\right)^{\circ}(\alpha \uplus \beta)$ does．But，（a）． 1 and（a）． 2 force $T_{\mathcal{E}^{\text {口 }}}=(\Delta \theta)^{\circ}(\alpha \uplus \beta)$ ， which makes（b）equivalent to（b）．1．And（a）． 2 and（ii）force $T_{\mathcal{E}^{\square}}=(\Delta \theta)^{\circ}(\alpha \uplus \beta)$ ，contra－ dicting（b）． 1 ，as desired．

ERL and ERR．We give the proof of soundness for ERL；the proof for ERR is entirely similar．By the minimality assumption we have：（i）$[\bar{X}, \mathcal{E}, H] \not \models(u=v) \theta, \Gamma \rightarrow \Lambda$ ，（ii） $[\bar{X}, \mathcal{E}, H] \models\left(u^{\prime}=v^{\prime}\right) \theta, \Gamma \rightarrow \Lambda$ and（iii）$[\varnothing, \mathcal{E}, \varnothing] \mid=u=v \Leftrightarrow u^{\prime}=v^{\prime}$ ．This means that there is a model $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ of $[\bar{X}, \mathcal{E}, H]$ and a ground constructor substitution $\beta$ with domain the variables of $(u=v) \theta, \Gamma \rightarrow \Lambda$ such that：（a）$T_{\mathcal{E}^{\text {口 }}} \not \models((u=v) \theta, \Gamma \rightarrow \Lambda)^{\circ}(\alpha \uplus \beta)$ ，and（b） $T_{\mathcal{E}^{\square}}=\left(\left(u^{\prime}=v^{\prime}\right) \theta, \Gamma \rightarrow \Lambda\right)^{\circ}(\alpha \uplus \beta)$（note that by the $\operatorname{vars}(u=v) \supseteq \operatorname{vars}(u=v)$ assumption， the same $\beta$ works for both satisfaction statements）．But this is impossible，since，by（iii）， in the inductive evaluation of the Tarskian semantics of（a）we can replace the truth value of $(u=v) \theta(\alpha \uplus \beta)$ by that of $\left(u^{\prime}=v^{\prime}\right) \theta(\alpha \uplus \beta)$ ，so that the formulas in（a）and（b）must evaluate to the same truth value，contradicting（a），as desired．

ICC．By the minimality assumption we have $[\bar{X}, \mathcal{E}, H] \not \models \Gamma \rightarrow \Lambda$ ，and $[\bar{X}, \mathcal{E}, H] \models$ $\bigwedge_{i \in I} \Gamma_{i}^{\sharp} \rightarrow \Lambda_{i}^{\sharp}$ ．We will show that this is impossible if we show the equivalence $(\dagger)[\bar{X}, \mathcal{E}, H] \models$
$\Gamma \rightarrow \Lambda \Leftrightarrow[\bar{X}, \mathcal{E}, H] \models \bigwedge_{i \in I} \Gamma_{i}^{\sharp} \rightarrow \Lambda_{i}^{\sharp}$. But (1) $[\bar{X}, \mathcal{E}, H] \models \Gamma \rightarrow \Lambda$ holds iff (2) $[\bar{X} \uplus \bar{Y}, \mathcal{E}, H \uplus\{\bar{\Gamma}\}] \vDash \bar{\Lambda}$ does, where $Y=\operatorname{vars}(\Gamma \rightarrow \Lambda)$, and $\bar{\Gamma}$ (resp. $\bar{\Lambda}$ ) is obtained from $\Gamma$ (resp. $\Lambda$ ) by replacing each $y \in Y$ by its corresponding constant $\bar{y} \in \bar{Y}$. And since $c c_{B_{0}}^{>}(\bar{\Gamma})$ is the ground Knuth-Bendix completion modulo $B_{0}$ of $\bar{\Gamma}$, by construction we have the equivalence $B_{0} \models \bigwedge \bar{\Gamma} \Leftrightarrow \bigwedge c c_{B_{0}}^{>}(\bar{\Gamma})$, and, since $B_{0}$ belongs to $\mathcal{E}$, a fortiori we have the equivalence $[\bar{X} \uplus \bar{Y}, \mathcal{E}, H] \vDash \bigwedge \bar{\Gamma} \Leftrightarrow \bigwedge c c_{B_{0}}^{>}(\bar{\Gamma})$. Therefore, (2) holds iff (3) $[\bar{X} \uplus$ $\left.\bar{Y}, \mathcal{E}, H \uplus\left\{c c_{B_{0}}^{>}(\bar{\Gamma})\right\}\right] \models \bar{\Lambda}$ does. Furthermore, by Lemma2 and the construction of $\bar{\Gamma}^{\sharp}$ we have the equivalence $\left[\bar{X} \uplus \bar{Y}, \mathcal{E}, H \uplus\left\{c c_{B_{0}}^{>}(\bar{\Gamma})\right\}\right] \models \bigwedge c c_{B_{0}}^{>}(\bar{\Gamma}) \Leftrightarrow \bar{\Gamma}^{\sharp}$. Therefore, (3) holds iff (4) $\left[\bar{X} \uplus \bar{Y}, \mathcal{E}, H \uplus \bar{\Gamma}^{\sharp}\right] \models \bar{\Lambda}$ does. Of course, if $\bar{\Gamma}^{\sharp}=\perp$ (4) trivially holds. But this is the case where, by convention, $[\bar{X}, \mathcal{E}, H] \models \bigwedge_{i \in I} \Gamma_{i}^{\sharp} \rightarrow \Lambda_{i}^{\sharp}$ denotes $\top$; so in this case have thus proved that (1) holds and therefore ( $\dagger$ ). From now on we may assume that $\bar{\Gamma}^{\sharp}=\bigvee_{i \in I} \bar{\Gamma}_{i}^{\sharp}$ with $I \neq \varnothing$. Therefore, (4) holds iff (5) $[\bar{X} \uplus \bar{Y}, \mathcal{E}, H] \models \bigwedge_{i \in I} \bar{I}_{i}^{\sharp} \rightarrow \bar{\Lambda}$ does. But, by Lemma 2 for each $i \in I,\left[\bar{X} \uplus \bar{Y}, \mathcal{E}, H \uplus \bar{\Gamma}_{i}^{\sharp}\right]=\bar{\Lambda}$ holds iff $\left[\bar{X} \uplus \bar{Y}, \mathcal{E}, H \uplus \bar{\Gamma}_{i}^{\sharp}\right]=\bar{\Lambda}_{i}^{\sharp}$ does, and therefore $[\bar{X} \uplus \bar{Y}, \mathcal{E}, H] \models \bar{\Gamma}_{i}^{\sharp} \rightarrow \bar{\Lambda}$ holds iff $[\bar{X} \uplus \bar{Y}, \mathcal{E}, H] \models \bar{\Gamma}_{i}^{\sharp} \rightarrow \bar{\Lambda}_{i}^{\sharp}$ does. Therefore, (5) holds iff (6) $[\bar{X} \uplus \bar{Y}, \mathcal{E}, H] \models \bigwedge_{i \in I} \bar{I}_{i}^{\sharp} \rightarrow \bar{\Lambda}_{i}^{\sharp}$ does; which itself holds iff (7) $[\bar{X}, \mathcal{E}, H] \models \bigwedge_{i \in I} \Gamma_{i}^{\sharp} \rightarrow \Lambda_{i}^{\sharp}$ does. This means that we have proved the equivalence $(\dagger)$ for all cases, as desired.

VARSAT. The contradiction of the minimality assumption is in this case is quite immediate, since for an $\mathcal{E}_{1}$-formula $\Gamma^{\circ} \rightarrow \Lambda^{\circ}$ its negation is unsatisfiable in $T_{\mathcal{E}}$ iff $T_{\mathcal{E}}=\Gamma^{\circ} \rightarrow \Lambda^{\circ}$, which, a fortiori, implies that any model $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ of $[\bar{X}, \mathcal{E}, H]$ must satisfy $\Gamma \rightarrow \Lambda$, contradicting the minimality assumption that $[\bar{X}, \mathcal{E}, H] \not \models \Gamma \rightarrow \Lambda$, as desired.

GSI. By the minimality assumption we have: (i) $[\bar{X}, \mathcal{E}, H] \not \models \Gamma \rightarrow \bigwedge_{j \in J} \Delta_{j}$; and (ii) $\left\{\left[\bar{X}_{\uplus}\right.\right.$ $\left.\left.\bar{Y}_{i}^{\bullet}, \mathcal{E}, H \uplus H_{i}\right]=\left(\Gamma \rightarrow \bigwedge_{j \in J} \Lambda_{j}\right)\left\{z \mapsto \bar{u}_{i}^{\bullet}\right\}\right\}_{1 \leqslant i \leqslant n}$, where $z$ is a variable of sort $s$. But (i) exactly means that there is a model $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ of $[\bar{X}, \mathcal{E}, H]$ such that $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right) \not \models \Gamma \rightarrow \bigwedge_{j \in J} \Delta_{j}$. Therefore, there is a ground constructor substitution $\beta$ with domain the variables $Z$ of $\Gamma \rightarrow \bigwedge_{j \in J} \Delta_{j}$ such that (a) $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right),[\beta] \not \models \Gamma \rightarrow \bigwedge_{j \in J} \Delta_{j}$. We can choose among such $\beta$ one such that the term size $|\beta(z)|$ is a smallest possible number $m$. Let us denote such a choice by $\beta_{\text {min }}$. This means that (b) for any $\beta^{\prime} \in\left[Z \rightarrow T_{\Omega}\right]$ such that $\left|\beta^{\prime}(z)\right|<m$ we must have $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right),\left[\beta^{\prime}\right] \models \Gamma \rightarrow \bigwedge_{j \in J} \Delta_{j}$. Furthermore, there is a $u_{k}$ in the $B_{0}$-generator set $\left\{u_{1}, \ldots u_{n}\right\}$ for sort $s$ and a ground substitution $\rho$ with domain $Y_{k}$ such that: (c) $\beta_{\min }(z)={ }_{B_{0}} u_{k} \rho$ and, since $B_{0}$ is size-preserving, (d) $\left|u_{k} \rho\right|=m$, and since each $v \in P S T_{B_{0}, \leqslant s}\left(u_{k}\right)$ is a proper $B_{0^{-}}$ subterm of $u_{k},|\rho(v)|<m$ for each $v \in P S T_{B_{0}, \leqslant s}\left(u_{k}\right)$. We now can distinguish two cases:
Case (1): $Y_{k} \neq \varnothing$ and the hypotheses

$$
H_{k}=\left\{\left(\left(\Gamma \rightarrow \Delta_{j}\right)\{z \rightarrow \bar{v}\}\right)!_{\overrightarrow{\mathcal{X}}_{\overline{\bar{X}}_{\uplus} \overline{\bar{r}}_{i U}}} \mid v \in P S T_{B_{0}, \leqslant s}\left(u_{k}\right) \wedge j \in J\right\}
$$

are non-trivial (therefore, $\operatorname{PST}_{B_{0}, \leqslant s}\left(u_{k}\right) \neq \varnothing$ ). Then, $\bar{Y}_{k}^{\bullet}=\bar{Y}_{k}$ and $\overline{u_{k}}{ }^{\bullet}=\overline{u_{k}}$. We claim that $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha} \uplus \bar{\rho}]\right)$ is a model of $\left[\bar{X} \uplus \bar{Y}_{k}, \mathcal{E}, H \uplus\left\{\left(\Gamma \rightarrow \Delta_{j}\right)\{z \mapsto \bar{v}\}\right\}_{v \in P S T_{B_{0}, \leqslant s}\left(u_{k}\right)}^{j \in J}\right]$. This is the case because: (e) $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha} \uplus \bar{\rho}]\right) \models H$ since $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right) \models H$, and (f) $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha} \uplus \bar{\rho}]\right) \models$ $\left\{\left(\Gamma \rightarrow \Delta_{j}\right)\{z \mapsto \bar{v}\}\right\}_{v \in P S T_{B_{0}, \leqslant s}\left(u_{k}\right)}^{j \in J}$, that is, $T_{\mathcal{E}^{\mathrm{a}}}=\left\{\left(\Gamma \rightarrow \Delta_{j}\right)^{\circ}\{z \mapsto v\}(\alpha \uplus \rho)\right\}_{v \in P S T_{B_{0}, \leqslant s}\left(u_{k}\right)}^{j \in J}$. (f) holds because, for each $v \in P S T_{B_{0}, \leqslant s}\left(u_{k}\right), \operatorname{vars}\left(\left(\Gamma \rightarrow \Delta_{j}\right)\{z \mapsto \bar{v}\}\right) \subseteq Z \backslash\{z\}$, and since the variables $Y_{k}$ are fresh and therefore do not appear in $\Gamma \rightarrow \Delta_{j}, j \in J$, (f) is equivalent to
$T_{\mathcal{E}^{\square}}=\left\{\left(\Gamma \rightarrow \Delta_{j}\right)^{\circ}(\{z \mapsto \rho(v)\} \uplus \alpha)\right\}_{v \in P S T_{B_{0}, \leqslant s}\left(u_{k}\right)}^{j \in J}$, wich must hold because any constructor ground substitution $\gamma$ of the variables $Z \backslash\{z\}$ gives us a ground substitution $\beta^{\prime}=\{z \rightarrow$ $\rho(v)\} \uplus \gamma$ with domain $Z$ such that we must have $T_{\mathcal{E}^{\mathrm{a}}} \models\left\{\left(\Gamma \rightarrow \Delta_{j}\right)^{\circ}(\{z \mapsto \rho(v)\} \uplus \alpha \uplus\right.$ $\gamma)\}_{v \in P S T_{B_{0}, \leqslant s}\left(u_{k}\right)}^{j \in J}$, that is, $T_{\mathcal{E}^{\square}}=\left\{\left(\Gamma \rightarrow \Delta_{j}\right)^{\circ}\left(\alpha \uplus \beta^{\prime}\right)\right\}_{v \in P S T_{B_{0}, \leqslant s}\left(u_{k}\right)}^{j \in J}$, which must hold by (b), since $\left|\beta^{\prime}(v)\right|=|\rho(v)|<m$ for each $v \in P S T_{B_{0}, \leqslant s}\left(u_{k}\right)$. Therefore, (ii) forces $(\mathrm{g})\left(T_{\mathcal{E}^{\square}},[\bar{\alpha} \uplus\right.$ $\bar{\rho}]) \vDash\left(\Gamma \rightarrow \bigwedge_{j \in J} \Delta_{j}\right)\left\{z \mapsto \bar{u}_{k}\right\}$, that is, $T_{\mathcal{E}^{\square}} \models\left(\Gamma \rightarrow \bigwedge_{j \in J} \Delta_{j}\right)^{\circ}\left\{z \mapsto u_{k}\right\}(\alpha \uplus \rho)$, which, again, since the variables $Y_{k}$ are fresh and therefore do not appear in $\left(\Gamma \rightarrow \bigwedge_{j \in J} \Delta_{j}\right)^{\circ}$, is just $T_{\mathcal{E}^{\square}} \models\left(\Gamma \rightarrow \bigwedge_{j \in J} \Delta_{j}\right)^{\circ}\left(\left\{z \mapsto u_{k} \rho\right\} \uplus \alpha\right)$; but since $\beta_{\text {min }}=\left.{ }_{B_{0}}\left\{z \mapsto u_{k} \rho\right\} \uplus \beta\right|_{Z \backslash\{z\}},(\mathrm{g})$ is equivalent to $T_{\mathcal{E}^{\square}}=\left(\Gamma \rightarrow \bigwedge_{j \in J} \Delta_{j}\right)^{\circ}\left(\alpha \uplus \beta_{\text {min }}\right)$, contradicting (a), as desired.

Case (2): Either $Y_{k}=\varnothing$ or the hypotheses $H_{k}$ are trivial, so that $\bar{Y}_{k}^{\bullet}=\varnothing$ and ${\overline{u_{k}}}^{\bullet}=u_{k}$. Therefore, for $i=k$, (ii) becomes: $[\bar{X}, \mathcal{E}, H] \models\left(\Gamma \rightarrow \bigwedge_{j \in J} \Delta_{j}\right)\left\{z \mapsto u_{k}\right\}$ ). But since $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ is a model of $[\bar{X}, \mathcal{E}, H]$, for the ground constructor substitution $\left.\beta_{\text {min }}\right|_{Z \backslash\{z\}} \uplus$ $\rho$ (where in case $Y_{k}=\varnothing, \rho$ is the empty substitution) we must have $T_{\mathcal{E}^{\square}} \vDash(\Gamma \rightarrow$ $\left.\bigwedge_{j \in J} \Delta_{j}\right)^{\circ}\left\{z \mapsto u_{k}\right\}\left(\left.\alpha \uplus \beta_{\text {min }}\right|_{Z \backslash\{z\}} \uplus \rho\right)$, which since the variables $Y_{k}$, if any, are fresh, just means $T_{\mathcal{E}^{\text {口 }}}=\left(\Gamma \rightarrow \bigwedge_{j \in J} \Delta_{j}\right)^{\circ}\left(\left\{z \mapsto u_{k} \rho\right\} \uplus \alpha \uplus \beta_{\text {min }} \mid Z \backslash\{z\}\right)$. But since $\beta_{\text {min }}={ }_{B_{0}}\left\{z \mapsto u_{k} \rho\right\} \uplus$ $\left.\beta\right|_{Z \backslash\{z\}}$ this is equivalent to $T_{\mathcal{E}^{\square}}=\left(\Gamma \rightarrow \bigwedge_{j \in J} \Delta_{j}\right)^{\circ}\left(\alpha \uplus \beta_{\text {min }}\right)$, contradicting (a), as desired.

NI. By the minimality assumption we have: (i) $[\bar{X}, \mathcal{E}, H] \not \models\left(\Gamma \rightarrow \bigwedge_{l \in L} \Delta_{l}\right)[f(\vec{v})]_{p}$, and (ii) $\left\{\left[\bar{X} \uplus \bar{Y}_{i, j}^{\bullet}, \mathcal{E},\left(H \uplus H_{i, j}\right] \models\left(\Gamma_{i},\left(\Gamma \rightarrow \bigwedge_{l \in L} \Delta_{l}\right)\left[r_{i}\right]_{p}\right) \bar{\alpha}_{i, j}^{\bullet}\right\}_{i \in I_{0}}^{j \in J_{i}}\right.$. But (i) exactly means that there is a model $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ of $[\bar{X}, \mathcal{E}, H]$ such that $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right) \not \models\left(\Gamma \rightarrow \bigwedge_{l \in L} \Delta_{l}\right)[f(\vec{v})]_{p}$. Therefore, there is a ground constructor substitution $\beta$ with domain the variables $Z$ of $\Gamma \rightarrow \bigwedge_{j \in L} \Delta_{l}$ such that (a) $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right),[\beta] \not \models\left(\Gamma \rightarrow \bigwedge_{l \in L} \Delta_{l}\right)[f(\vec{v})]_{p}$. We can choose among such $\beta$ one such that the term size $|f(\vec{v}) \beta|$ is a smallest possible number $m$. Let us denote such a choice by $\beta_{\text {min }}$. This means that (b) for any $\beta^{\prime} \in\left[Z \rightarrow T_{\Omega}\right]$ such that $\left|f(\vec{v}) \beta^{\prime}\right|<m$ we must have $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right),\left[\beta^{\prime}\right] \models\left(\Gamma \rightarrow \bigwedge_{l \in L} \Delta_{l}\right)[f(\vec{v})]_{p}$. Furthermore, by sufficient completeness, there must be a rule $[i]: f\left(\vec{u}_{i}\right) \rightarrow r_{i}$ if $\Gamma_{i}$ among those defining $f$, a unifier $\alpha_{i, j} \in \operatorname{Unif}_{B_{0}}\left(f(\vec{v})=f\left(\overrightarrow{u_{i}}\right)\right)$ with $\operatorname{ran}\left(\alpha_{i, j}\right)=Y_{i, j}$ fresh variables, and a constructor ground substitution $\rho \in\left[Y_{i, j} \rightarrow T_{\Omega}\right]$ such that, defining $Z_{\overrightarrow{\mathcal{p}}}=\operatorname{vars}(f(\vec{v}))$, we have: (c). $\left.1 \beta_{\min }\right|_{Z_{\vec{v}}}={ }_{B_{0}}$ $\left.\left(\alpha_{i, j} \rho\right)\right|_{Z_{\vec{i}}}$, and therefore $\beta_{\text {min }}=\left.\left.{ }_{B_{0}} \beta_{\text {min }}\right|_{Z \backslash Z_{\vec{v}}} \uplus\left(\alpha_{i, j} \rho\right)\right|_{Z_{\vec{i}}} ;(\mathrm{c}) .2 f(\vec{v}) \beta_{\text {min }}={ }_{B_{0}} f\left(\overrightarrow{u_{i}}\right) \alpha_{i, j} \rho$, so that $\left|f\left(\overrightarrow{u_{i}}\right) \alpha_{i, j} \rho\right|=m$; (c). $3 \Gamma_{i} \beta_{\min }={ }_{B_{0}} \Gamma_{i} \alpha_{i, j} \rho$, and $\mathcal{E} \vdash \Gamma_{i} \alpha_{i, j} \rho$ (since rule $[i]$ applies); and therefore (c). $4 f(\vec{v}) \beta_{\text {min }}=\varepsilon r_{i} \beta_{\text {min }}$. We can now distinguish two cases:
Case (1): The simplified hypotheses $\left(H_{i, j}\right)!_{\overrightarrow{\mathcal{E}}_{\overline{\bar{X}}}^{\uplus} \bar{Y}_{i, j_{U}}}$ are nontrivial, so that $\bar{Y}_{i, j}^{\bullet}=\bar{Y}_{i, j}$ and $\bar{\alpha}_{i, j}^{\bullet}=\bar{\alpha}_{i, j}$. We claim that $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha} \uplus \bar{\rho}]\right)$ is a model of $\left[\bar{X} \uplus \bar{Y}_{i, j}, \mathcal{E}, H \uplus H_{i, j}\right]$. Fists of all, $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha} \uplus \bar{\rho}]\right) \mid=H$ since $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right) \mid=H$. Let us see that we also have $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha} \uplus \bar{\rho}]\right) \mid=H_{i, j}$. That is, we need to show that for each induction hypothesis $\left(\Gamma \rightarrow \Delta_{l}\right) \bar{\gamma}$ in $H_{i, j}$, and for each ground constructor substitution $\delta \in\left[\left(Z \backslash Z_{\vec{v}}\right) \rightarrow T_{\Omega}\right], T_{\mathcal{E}^{\square}}=\left(\Gamma \rightarrow \Delta_{l}\right)^{\circ} \gamma(\alpha \uplus \rho \uplus \delta)$ holds, which by the freshness assumption on $Y_{i, j}$ just means that (d) $T_{\mathcal{E}^{\square}} \models(\Gamma \rightarrow$ $\left.\Delta_{l}\right)^{\circ}(\alpha \uplus(\gamma \rho) \uplus \delta)$ holds. Furthermore, by the definition of the matching substitution $\gamma$ we must have $f(\vec{v}) \gamma(\alpha \uplus \rho \uplus \delta)=f(\vec{v}) \gamma \rho=f(\vec{w}) \alpha_{i, j} \gamma$, with $f(\vec{w})$ a proper subcall of rule $[i]$, so that, by (c). $2,\left|f(\vec{w}) \alpha_{i, j} \rho\right|<m$. But, since $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ is a model of $[\bar{X}, \mathcal{E}, H]$, viewing $(\gamma \rho) \uplus \delta$ as a decomposition of a ground substitution $\beta^{\prime}$ with domain $Z$ and noticing that $\left|f(\vec{v}) \beta^{\prime}\right|=|f(\vec{v}) \gamma \rho|<m$, (d) indeed holds because of (b). Therefore, by (ii), we must have $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha} \uplus \bar{\rho}]\right) \mid=\left(\Gamma_{i},\left(\Gamma \rightarrow \bigwedge_{\left.l \in L^{\Delta_{l}}\right)}\left[r_{i}\right]_{p}\right) \bar{\alpha}_{i, j}\right.$. In particular, since vars $\left(\left(\Gamma_{i},(\Gamma \rightarrow\right.\right.$
$\left.\left.\left.\bigwedge_{l \in L} \Delta_{l}\right)\left[r_{i}\right]_{p}\right) \bar{\alpha}_{i, j}\right)=Z \backslash Z_{\vec{v}}$, this must be the case for the ground constructor substitution $\left.\beta_{\text {min }}\right|_{Z \backslash Z_{\vec{v}}}$. That is, we must have $T_{\mathcal{E}^{\square}} \models\left(\Gamma_{i},\left(\Gamma^{\circ} \rightarrow \bigwedge_{l \in L} \Delta_{l}^{\circ}\right)\left[r_{i}\right]_{p}\right) \alpha_{i, j}\left(\left.\alpha \uplus \rho \uplus \beta_{\text {min }}\right|_{Z \backslash Z_{\vec{v}}}\right)$, that is, $T_{\mathcal{E}^{\square}}=\left(\Gamma_{i},\left(\Gamma^{\circ} \rightarrow \bigwedge_{l \in L} \Delta_{l}^{\circ}\right)\left[r_{i}\right]_{p}\right)\left(\left.\alpha \uplus\left(\alpha_{i, j} \rho\right) \uplus \beta_{\text {min }}\right|_{Z \backslash Z_{i}}\right)$. But, by (c).3, this is equivalent to $T_{\mathcal{E}^{\square}} \models\left(\Gamma^{\circ} \rightarrow \bigwedge_{l \in L} \Delta_{l}^{\circ}\right)\left[r_{i}\right]_{p}\left(\left.\alpha \uplus\left(\alpha_{i, j} \rho\right) \uplus \beta_{\min }\right|_{Z \backslash Z_{i}}\right)$, which by (c). 1 is equivalent to $T_{\mathcal{E}^{\square}} \models\left(\Gamma^{\circ} \rightarrow \bigwedge_{l \in L} \Delta_{l}^{\circ}\right)\left[r_{i}\right]_{p}\left(\alpha \uplus \beta_{\text {min }}\right)$, which by (c). 4 is equivalent to $T_{\mathcal{E}^{\square}}=\left(\Gamma^{\circ} \rightarrow \bigwedge_{l \in L} \Delta_{l}^{\circ}\right)[f(\vec{v})]_{p}\left(\alpha \uplus \beta_{\text {min }}\right)$, contradicting (a), as desired.
Case (2): the simplified hypotheses $\left(H_{i, j}\right)!_{\overrightarrow{\bar{X}}_{\bar{X}_{\uplus}}}$ are trivial, so that $Y_{i, j}^{\bullet}=\varnothing$ and $\bar{\alpha}_{i, j}^{\bullet}=$ $\alpha_{i, j}$. This means that, for rule [i], (ii) gives us $[\bar{X}, \mathcal{E}, H] \models\left(\Gamma_{i},\left(\Gamma \rightarrow \bigwedge_{l \in L} \Delta_{l}\right)\left[r_{i}\right]_{p}\right) \alpha_{i, j}$. But, since $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ is a model of $[\bar{X}, \mathcal{E}, H]$ and $\operatorname{vars}\left(\left(\Gamma_{i},\left(\Gamma \rightarrow \bigwedge_{l \in L} \Delta_{l}\right)\left[r_{i}\right]_{p}\right) \alpha_{i, j}\right) \subseteq$ $\left(Z \backslash Z_{\vec{v}}\right) \uplus Y_{i, j}$, in particular, for the ground constructor substitution $\left.\beta_{\text {min }}\right|_{Z \backslash Z_{\vec{v}}} \uplus\left(\alpha_{i, j} \rho\right)$ we must have $T_{\mathcal{E}^{\square}}=\left(\Gamma_{i},\left(\Gamma^{\circ} \rightarrow \bigwedge_{l \in L} \Delta_{l}^{\circ}\right)\left[r_{i}\right]_{p}\right)\left(\left.\alpha \uplus\left(\alpha_{i, j} \rho\right) \uplus \beta_{\min }\right|_{Z \backslash Z_{\vec{v}}}\right)$. But, by (c).3, this is equivalent to $T_{\mathcal{E}^{\square}} \models\left(\Gamma^{\circ} \rightarrow \bigwedge_{l \in L} \Delta_{l}^{\circ}\right)\left[r_{i}\right]_{p}\left(\left.\alpha \uplus\left(\alpha_{i, j} \rho\right) \uplus \beta_{\text {min }}\right|_{Z \backslash Z_{\dot{*}}}\right)$, which by (c). 1 is equivalent to $T_{\mathcal{E}^{\square}} \vDash\left(\Gamma^{\circ} \rightarrow \bigwedge_{l \in L} \Delta_{l}^{\circ}\right)\left[r_{i}\right]_{p}\left(\alpha \uplus \beta_{\text {min }}\right)$, which by (c). 4 is equivalent to $T_{\mathcal{E}^{\text {․ }}}=\left(\Gamma^{\circ} \rightarrow \bigwedge_{l \in L} \Delta_{l}^{\circ}\right)[f(\vec{v})]_{p}\left(\alpha \uplus \beta_{\text {min }}\right)$, contradicting (a), as desired.

Existential ( $\exists$ ). By the minimality assumption we have: (i) $[\varnothing, \mathcal{E}, \varnothing] \nLeftarrow(\exists \chi)(\Gamma \rightarrow \Lambda)$, that is, $T_{\mathcal{E}^{\square}} \not \models(\exists \chi)(\Gamma \rightarrow \Lambda)$; and (ii) $[\varnothing, \mathcal{E}, \varnothing] \vDash I(\Gamma \rightarrow \Lambda)$, that is, $T_{\mathcal{E}^{\square}}=I(\Gamma \rightarrow \Lambda)$, where $\chi$ is a Skolem signature, $\Gamma \rightarrow \Lambda$ is a $\Sigma \cup \chi$-multiclause, and $I: \chi \rightarrow \mathcal{E}$ is a theory interpretation. But, as pointed out in Section 2.11, $T_{\mathcal{E}^{\square}} \mid=I(\Gamma \rightarrow \Lambda)$ gives a constructive proof of $T_{\mathcal{E}^{\text {a }}}=(\exists \chi)(\Gamma \rightarrow \Lambda)$ by proving that the intepretation $I(f)$ of the symbols $f$ in the Skolem signature satisfies the interpretation $I(\Gamma \rightarrow \Lambda)$ of the $\Sigma \uplus \chi$-multiclause $\Gamma \rightarrow \Lambda$, in direct contradiction of (i), as desired.

LE. By the minimality assumption we have: (i) $[\bar{X}, \mathcal{E}, H] \not \models \Gamma \rightarrow \Lambda$; (ii) $\left[\bar{X}_{0}, \mathcal{E}, H_{0}\right] \models$ $\Gamma^{\prime} \rightarrow \bigwedge_{j \in J} \Delta_{j}^{\prime}$; (iii) $[\bar{X}, \mathcal{E}, H] \models H_{0}$; and (iv) $\left[\bar{X}, \mathcal{E}, H \uplus\left\{\Gamma^{\prime} \rightarrow \Delta_{j}^{\prime}\right\}_{j \in J}\right] \models \Gamma \rightarrow \Lambda$, where $\varnothing \subseteq \bar{X}_{0} \subseteq \bar{X}$. But (i) exactly means that there is a model $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ of $[\bar{X}, \mathcal{E}, H]$ such that (a) $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right) \not \models \Gamma \rightarrow \Lambda$. However, $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ is also a model of $\left[\bar{X}, \mathcal{E}, H \uplus\left\{\Gamma^{\prime} \rightarrow \Delta_{j}^{\prime}\right\}_{j \in J}\right]$. This is so because we obviously have (b) $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right) \models H$; which by (iii) forces $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right) \models H_{0}$; which, by (ii) and $\bar{X}_{0} \subseteq \bar{X}$, forces (c) $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right) \mid=\Gamma^{\prime} \rightarrow \Delta_{j}^{\prime}$ for each $j \in J$. Therefore, (iv) gives us $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right) \mid=\Gamma \rightarrow \Lambda$, in flat contradiction of (a), as desired.

SP. By the minimality assumption we have: (i) $[\bar{X}, \mathcal{E}, H] \not \models \Gamma \rightarrow \Lambda$; (ii) $\{[\bar{X}, \mathcal{E}, H] \models$ $\left.\Gamma_{i} \theta, \Gamma \rightarrow \Lambda\right\}_{i \in I}$; (iii) $[\bar{X}, \mathcal{E}, H] \mid=H_{0}$; and (iv) $\left[\bar{X}_{0}, \mathcal{E}, H_{0}\right] \models \bigvee_{i \in I} \Gamma_{i}$, where $\bar{X}_{0} \subseteq \bar{X}$, and $\operatorname{vars}\left(\left(\bigvee_{i \in I} \Gamma_{i}\right) \theta\right) \subseteq \operatorname{vars}(\Gamma \rightarrow \Lambda)=Y$. But (i) means we have constructor ground substitutions $\alpha$ and $\beta$ with respective domains $X$ and $Y$ such that: (a) $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ is a model of $[\bar{X}, \mathcal{E}, H]$, and (b) $T_{\mathcal{E}^{\square}} \not \models(\Gamma \rightarrow \Lambda)^{\circ}(\alpha \uplus \beta)$, that is, (b). $1 T_{\mathcal{E}^{\square}} \models(\Gamma)^{\circ}(\alpha \uplus \beta)$, and (b). 2 $T_{\mathcal{E}^{\square}} \not \models \Lambda^{\circ}(\alpha \uplus \beta)$. But, since by (iii) and (iv), we must have $T_{\mathcal{E}^{\square}}=\left(\left(\bigvee_{i \in I} \Gamma_{i}\right) \theta\right)^{\circ}(\alpha \uplus \beta)$, there must be an $i \in I$ such that $T_{\mathcal{E}^{\mathrm{a}}}=\left(\Gamma_{i} \theta\right)^{\circ}(\alpha \uplus \beta)$. Therefore, by (b).1, we have (c) $T_{\mathcal{E}^{\square}} \models\left(\Gamma_{i} \theta, \Gamma\right)^{\circ}(\alpha \uplus \beta)$, which by (ii) and $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ being a model of $[\bar{X}, \mathcal{E}, H]$ forces $T_{\mathcal{E}^{\square}}=\Lambda^{\circ}(\alpha \uplus \beta)$, contradicting (b).2, as desired.

CAS. We prove the two modalities: for a $z$ variable, and for $\bar{z} \in \bar{X}$.
Case (1). We have $z$ of sort $s$ occurring in $\Gamma \rightarrow \Lambda$, and $\left\{u_{1}, \cdots, u_{n}\right\}$ is a $B_{0}$-generator set for sort $s$, with each $u_{i}, 1 \leqslant i \leqslant n$, having fresh variables. By the minimality assumption we have: (i) $[\bar{X}, \mathcal{E}, H] \not \models \Gamma \rightarrow \Lambda$; and (ii) $\left\{[\bar{X}, \mathcal{E}, H] \vDash(\Gamma \rightarrow \Lambda)\left\{z \mapsto u_{i}\right\}\right\}_{1 \leqslant i \leqslant n}$. A moment's
reflection helps us realize that the task of proving this case coincides with the -already accomplished - task of proving Case (2) for the GSI rule, i.e., the case when either $Y_{i}=\varnothing$ or the induction hypotheses are trivial: the proof is identical here.

Case (2). We have $\bar{z} \in \bar{X}$ of sort $s$ occurs in $\Gamma \rightarrow \Lambda, Y_{i}=\operatorname{vars}\left(u_{i}\right), \bar{Y}_{i}$ are the corresponding new fresh constants, and $\bar{u}_{i} \equiv u_{i}\{y \mapsto \bar{y}\}_{y \in Y_{i}}$. By the minimality assumption we have: (i) $[\bar{X}, \mathcal{E}, H] \not \models \Gamma \rightarrow \Lambda$; and (ii) $\left\{\left[\bar{X} \uplus \bar{Y}_{i}, \mathcal{E}, H \uplus\left\{\bar{z}=\bar{u}_{i}\right\}\right] \models(\Gamma \rightarrow \Lambda)\left\{\bar{z} \mapsto \bar{u}_{i}\right\}\right\}_{1 \leqslant i \leqslant n}$. But (i) exactly means that there is a model $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ of $[\bar{X}, \mathcal{E}, H]$ such that $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right) \not \models \Gamma \rightarrow \Lambda$, that is, (a) $T_{\mathcal{E}^{\text {口 }}} \not \models(\Gamma \rightarrow \Lambda)^{\circ} \alpha$. But then there is a $k, 1 \leqslant k \leqslant n$, and a ground constructor substitution $\rho$ with domain $Y_{k}$ such that (b). $1 \alpha(x)={ }_{B_{0}} u_{k} \rho$; which implies (b). $2 \alpha={ }_{B_{0}}$ $\left.\alpha\right|_{X \backslash\{z\}} \uplus\left\{z \mapsto u_{k} \rho\right\}$. We claim that $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha} \uplus \bar{\rho}]\right)$ is a model of $\left[\bar{X} \uplus \bar{Y}_{i}, \mathcal{E}, H \uplus\left\{\bar{z}=\bar{u}_{k}\right\}\right]$. Indeed: (b) $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha} \uplus \bar{\rho}]\right) \models H$ because $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right) \models H$; and (c) $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha} \uplus \bar{\rho}]\right) \models \bar{z}=\bar{u}_{k}$, that is, $T_{\mathcal{E}^{\square}}=z=u_{k}(\alpha \uplus \rho)$, which holds by (b). 1 and $T_{\mathcal{E}^{\square}} \models B_{0}$. But then (ii) forces $\left(T_{\mathcal{E}^{\square}},[\bar{\alpha} \uplus \bar{\rho}]\right) \models(\Gamma \rightarrow \Lambda)\left\{\bar{z} \mapsto \bar{u}_{k}\right\}$, that is, $T_{\mathcal{E}^{\square}} \models(\Gamma \rightarrow \Lambda)^{\circ}\left\{z \mapsto u_{k}\right\}(\alpha \uplus \rho)$, which by (b). 2 is equivalent to $T_{\mathcal{E}^{\mathrm{a}}}=(\Gamma \rightarrow \Lambda)^{\circ} \alpha$, flatly contradicting (a), as desired.

VA. By the minimality assumption we have: (i) $[\bar{X}, \mathcal{E}, H] \not \models[\bar{X}, \mathcal{E}, H] \Vdash u=v[w]_{p}, \Gamma \rightarrow \Lambda$; and (ii) $[\bar{X}, \mathcal{E}, H] \models u=v[z]_{p}, z=w, \Gamma \rightarrow \Lambda$, where $z$ is fresh variable of sort the least sort of $w$. But (i) exactly means that, for $Y=\operatorname{vars}\left(u=v[w]_{p}, \Gamma \rightarrow \Lambda\right)$ we have constructor ground substitutions $\alpha$ and $\beta$ with respective domains $X$ and $Y$ such that: (a) ( $\left.T_{\mathcal{E}^{\square}},[\bar{\alpha}]\right)$ is a model of $[\bar{X}, \mathcal{E}, H]$, and (b) $T_{\mathcal{E}^{\text { }}} \not \models\left(u=[w]_{p}, \Gamma^{\prime} \rightarrow \Lambda\right)^{\circ}(\alpha \uplus \beta)$. That is, (b). $1 T_{\mathcal{E}^{\text { }}}=$ $\left(u=v[w]_{p}, \Gamma\right)^{\circ}(\alpha \uplus \beta)$, and (b). $2 T_{\mathcal{E}^{\square}} \not \models \Lambda^{\circ}(\alpha \uplus \beta)$. Consider now the constructor ground substitution $\alpha \uplus \beta \uplus\{z \mapsto w(\alpha \uplus \beta)\}$. Since $v[z]_{p}(\alpha \uplus \beta \uplus\{z \mapsto w(\alpha \uplus \beta)\})=v[w]_{p}(\alpha \uplus \beta)$, (b). 1 forces $T_{\mathcal{E}^{\square}} \models\left(u=v[z]_{p}, z=w, \Gamma\right)^{\circ}(\alpha \uplus \beta \uplus\{z \mapsto w(\alpha \uplus \beta)\})$. But then (ii) forces $T_{\mathcal{E}^{\square}} \models \Lambda^{\circ}(\alpha \uplus \beta \uplus\{z \mapsto w(\alpha \uplus \beta)\})$. But since $z$, being fresh, does not occur in $\Lambda^{\circ}$, this in turn forces $T_{\mathcal{E}^{\square}}=\Lambda^{\circ}(\alpha \uplus \beta)$, in direct contradiction with (b).2.

EQ. By the minimality assumption we have: (i) $[\bar{X}, \mathcal{E}, H] \not \models(\Gamma \rightarrow \Lambda)[w]_{p}$ and (ii) $[\bar{X}, \mathcal{E}, H] \equiv(\Gamma \rightarrow \Lambda)[v \theta \gamma]_{p}$, with $w={ }_{B_{0}} u \theta \gamma$. But, since the conditional equation $\Gamma^{\prime} \rightarrow$ $u=v$ used in this inference step belongs to either $\mathcal{E}$ or $H$, this is impossible, since, by Lemma 1 we have $[\bar{X}, \mathcal{E}, H] \models(\Gamma \rightarrow \Lambda)[v \theta \gamma]_{p} \Leftrightarrow(\Gamma \rightarrow \Lambda)[w]_{p}$, which by (ii) forces $[\bar{X}, \mathcal{E}, H] \models(\Gamma \rightarrow \Lambda)[w]_{p}$.

Cut. By the minimality assumption we have: (i) $[\bar{X}, \mathcal{E}, H] \not \models \Gamma \rightarrow \Lambda$, (ii) $[\bar{X}, \mathcal{E}, H] \mid=\Gamma \rightarrow \Gamma^{\prime}$ and (iii) $[\bar{X}, \mathcal{E}, H] \models \Gamma, \Gamma^{\prime} \rightarrow \Lambda$, with $\operatorname{vars}\left(\Gamma^{\prime}\right) \subseteq \operatorname{vars}(\Gamma \rightarrow \Lambda)=Y$. But (i)-(iii) are respectively equivalent to: (i') $[\bar{X} \uplus \bar{Y}, \mathcal{E}, H] \not \models \bar{\Gamma} \rightarrow \bar{\Lambda},\left(\mathrm{ii}^{\prime}\right)[\bar{X} \uplus \bar{Y}, \mathcal{E}, H] \vDash \bar{\Gamma} \rightarrow \overline{\Gamma^{\prime}}$ and (iii') $[\bar{X} \uplus$ $\bar{Y}, \mathcal{E}, H] \equiv \bar{\Gamma}, \overline{\Gamma^{\prime}} \rightarrow \bar{\Lambda}$, which is impossible, since $\left(\left(G \Rightarrow G^{\prime}\right) \wedge\left(\left(G \wedge G^{\prime}\right) \Rightarrow L\right)\right) \Rightarrow(G \Rightarrow L)$ is a tautology of Propositional Logic. Therefore, by the Tarskian semantics of formulas, (ii') and (iii') imply $[\bar{X} \uplus \bar{Y}, \mathcal{E}, H]=\bar{\Gamma} \rightarrow \bar{\Lambda}$, which is equivalent to $[\bar{X}, \mathcal{E}, H]=\Gamma \rightarrow \Lambda$.

This finishes the proof of the Soundness Theorem. $\square$

[^0]:    ${ }^{1}$ As explained in [54], there is no real loss of generality in assuming that all atomic formulas are equations: predicates can be specified by equational formulas using additional function symbols of a fresh new sort Pred with a constant $t t$, so that a predicate atom $p\left(t_{1}, \ldots, t_{n}\right)$ becomes $p\left(t_{1}, \ldots, t_{n}\right)=t t$.

[^1]:    ${ }^{2}$ If $B=B_{0} \uplus U$, with $B_{0}$ associativity and/or commutativity axioms, and $U$ identity axioms, the $B$-preregularity notion can be broadened by requiring only that: (i) $\Sigma$ is $B_{0}$-preregular in the standard sense that $l s(u \rho)=l s(v \rho)$ for all $u=v \in B_{0}$ and substitutions $\rho$; and (ii) the axioms $U$ oriented as rules $\vec{U}$ are sort-decreasing in the sense explained in Section 2.2

[^2]:    ${ }^{3}$ In [33] the equality predicate is denoted $\_\sim$, instead of the standard notation $\quad=\ldots$. Here we use $\boldsymbol{Z}_{-}$throughout. This has the pleasant effect that a QF formula $\varphi$ is both a formula and a Boolean expression, which of course amounts to mechanizing by equational rewriting the Tarskian semantics of QF formulas in first-order-logic for initial algebras.

[^3]:    ${ }^{4}$ That is, $T_{\mathcal{E}}=\left.\right|_{\Sigma} \cong T_{\mathcal{E}}$, and there is a subtheory inclusion $\mathcal{B} \subseteq \mathcal{E}^{=}$, with $\mathcal{B}$ having signature $\Sigma_{\mathcal{B}}$ and only sort NewBool such that: (i) $T_{\mathcal{B}}$ the initial algebra of the Booleans, and (ii) $T_{\mathcal{E}}=\left.\right|_{\Sigma_{\mathcal{B}}} \cong T_{\mathcal{B}}$.

[^4]:    ${ }^{5}$ The recursive path order (RPO) is a well-founded simplification order on terms parametric on an order on function symbols (see, e.g., [2]). RPO is a total order on terms if the order on symbols is so. RPO has been extended to RPO modulo AC in various papers, including [66].

[^5]:    ${ }^{6} \mathrm{An} \overrightarrow{\mathcal{E}}_{1}$-variant (or $\vec{E}_{1}, B_{1}$-variant) of a $\Sigma_{1}$-term $t$ is a pair $(v, \theta)$, where $\theta$ is a substitution in canonical form, i.e., $\theta=\theta!_{\vec{\varepsilon}_{1}}$, and $v={ }_{B_{1}}(t \theta)!_{\overrightarrow{\mathcal{E}}_{1}} \cdot \overrightarrow{\mathcal{E}_{1}}$ is FVP iff any such $t$ has a finite set of variants $\left\{\left(u_{1}, \alpha_{1}\right), \ldots,\left(u_{n}, \alpha_{n}\right)\right\}$ which are "most general possible" in the precise sense that for any variant $(v, \theta)$ of $t$ there exist $i, 1 \leqslant i \leqslant n$, and substitution $\gamma$ such that: (i) $v={ }_{B_{1}} u_{i} \gamma$, and (ii) $\theta={ }_{B_{1}} \alpha_{i} \gamma$.
    7 The notion of an FVP theory has been recently extended in [56] to allow also axioms of associativity without commutativity in $B_{1}$.
    ${ }^{8}$ When $B_{1}$ contains associativity without commutativity axioms, the number of unifiers in Unif $f_{\mathcal{E}_{1}}^{\varrho}(\Gamma)$ may be infinite. However, Maude's $B_{1}$-unification algorithm used in the process of computing $U n i f_{\mathcal{E}_{1}}^{Q}(\Gamma)$ will always produce a finite set of solutions, together with an incompleteness warning in case some solutions are missing. This warning will imply that the finite set of unifiers $U n i f_{\mathcal{E}_{1}}^{\Omega}(\Gamma)$ is incomplete.

[^6]:    ${ }^{9}$ More precisely, from their definition, not in the original theory $\mathcal{E}$, but in the transformed theory $\mathcal{E}_{U}$, making sure that no lefthandside for an equation defining $f$ collapses under the $\mathcal{E} \mapsto \mathcal{E}_{U}$ transformation to a lefthand side not topped by $f$ due to an $U$-axiom for $f$.
    ${ }^{10}$ Rule $[l]$ may also have other subcalls where some arguments are terms with defined symbols.
    ${ }^{11}$ However, as mentioned in Footnote 9 we should check that in the $\overrightarrow{\mathcal{E}} \mapsto \overrightarrow{\mathcal{E}}_{U}$ transformation, no lefthandside of a rule in $\overrightarrow{\mathcal{E}}$ defining $f$ has as one of its transformed rules a rule whose lefthand side is not topped by $f$ due to an $U$-axiom for $f$.

[^7]:    ${ }^{12}$ Ordered rewriting can be defined even more broadly than as presented here. However, the cases we discuss apply very broadly —and modulo axioms $B$ - and are quite easy to implement.

[^8]:    ${ }^{13}$ In the inductive inference system presented in Section 4, the first and second simplifications can both be achieved by the equality predicate simplification rule (EPS).

[^9]:    ${ }^{14}$ In a rewrite theory $\mathcal{R}=(\Sigma, E \cup B, R)$ where the equational rules $\vec{E}$ are convergent modulo $B$, a non-equational and possibly conditional rule $l \rightarrow r$ if cond can have an equational condition cond. This means that only the equational rules $\vec{E}$ will be applied (modulo $B$ ) to evaluate such an equational condition. In our example, the matching condition $z:=y+\bar{x}$ is an equational condition, which will be evaluated using only equational rules such as those in the background theory $\mathcal{N}$. This distinction between equational rules and non-equational ones will be exploited in Sections 34 It is useful not just to make ordered rewriting "theory aware," but for the much broader reason that, while the rules $\vec{E}$ are assumed ground confluent, confluence is often lost when induction hypotheses are added, so that there is no such thing anymore as the canonical form of a term. Exploring all the different canonical forms of a term is what the distinction between equational and non-equational rules makes possible.

[^10]:    ${ }^{15}$ Using the multiclause representation is optional: a user of the inference system may choose to stick to the less general clause representation. However, I explain in Section 5 that using multiclauses can afford a substantial economy of thought and lead to shorter proofs.

[^11]:    ${ }^{16}$ Even when, say, an induction hypothesis in H might originally be a multiclause $\Gamma \rightarrow \bigwedge_{l \in L} \Delta_{l}$, for executability reasons it will always be decomposed into its corresponding set of clauses $\left\{\Gamma \rightarrow \Delta_{l}\right\}_{l \in L}$.
    ${ }^{17}$ The reader might wonder about the reasons for extending $\mathcal{E}$ to $\mathcal{E}^{\square}$. There are at least two good reasons. First, as shown in [53], the congruence closure modulo axioms $B$ of a set of ground $\Sigma$-equations is not in general a set of ground $\Sigma$-rewrite rules, but only a set of ground $\Sigma^{\square}$-rewrite rules. Therefore, even if the original goal to be proved is a $\Sigma$-multiclause, some of its subgoals may be $\Sigma^{\square}$-multiclauses -obtained, for example, by application of the ICC simplification rule (see Section 4). Second, the extra generality of the theory $\mathcal{E}^{\square}$ supports the verification of sufficient completeness properties as inductive theorems for specifications $\mathcal{E}$ outside the scope of tree-automata techniques such as [37], a topic developed elsewhere [55].
    18 A crucial property of a total RPO order modulo $B_{0}$, for $B_{0}$ any combination of associativity and/or commutativity axioms, is that it defines a total order on $B_{0}$-equivalence classes of ground terms [66|65]. This property has many useful consequences for the present work.

[^12]:    ${ }^{19}$ That is, formulas appearing in a conjectured inductive theorem or in subgoals of such a conjecture. Note that rewriting modulo axioms with both the module's ground convergent oriented equations $\vec{E}$ and executable hypotheses in $H$ can simplify both terms in a goal and the goal $\Gamma \rightarrow \Delta$ itself. However, as further explained below, since we regard goal $\Gamma \rightarrow \Delta$ as a Boolean term in the convergent equational theory extending the goal's theory $\mathcal{E}$ with equationally-defined equality predicates, formula simplification can be even more powerful than term simplification, since we can also use the oriented equations defining equality predicates to simplify not only terms but also equations inside a goal.

[^13]:    ${ }^{20}$ Note that, since $\left(\Sigma^{=}(\bar{X}), E^{=} \cup B_{0}^{=}\right)$already has an equality predicate ${ }_{-}=-$we do not need to add a new sort Pred or an equality predicate $\equiv_{-}$as done in Section 2.10 to define such conditions: we just use the sort NewBool and the equality predicate ${ }_{-}=_{-}$in $\left(\Sigma^{=}(\bar{X}), E^{=} \cup B_{0}^{=}\right)$instead.

[^14]:    ${ }^{21}$ Note that all unconditional ground equations in $H$ are always orientable as ( $U$-transformed) reductive ground rewrite rules in $\vec{H}_{g e_{U}}$. This is because, as explained in Footnote $18, B_{0}$ equivalence classes of $\Sigma$-terms are totally ordered in a total RPO order modulo $B_{0}$, and we assume that the total order on symbols in $\Sigma$ has been extended to a total order on symbols in $\Sigma(\bar{X})$.

[^15]:    ${ }^{22}$ For example, that the number of the goals in the conjunction is smallest possible.
    ${ }^{23}$ This requirement will be relaxed in the future to allow equational programs whose constructors are not free modulo axioms. The main reason for currently imposing this restriction is precisely to allow application of the EPS simplification rule, which simplifies formulas with the rules in $\overrightarrow{\mathcal{E}}_{U}^{=}$(plus executable induction hypotheses), since $\overrightarrow{\mathcal{E}}_{U}^{=}$assumes that $\mathcal{E}_{U}$ has free constructors modulo $B_{0}$.
    ${ }^{24}$ Recall that $\Gamma$ is a conjunction and $\Lambda$ a conjunction of disjunctions. Therefore, the equality predicate rewrite rules together with ${\overrightarrow{H_{e}}}_{+}^{+}$may have powerful "cascade effects." For example, if either $\perp \in \Gamma!_{\vec{\varepsilon}_{\overline{\bar{x}_{U}}} \cup \overrightarrow{\hat{H}}_{e_{U}}^{+}}$or $T \in \Lambda!_{\vec{\varepsilon}_{\overrightarrow{\bar{x}}_{U}} \cup \vec{H}_{e_{U}}^{+}}$, then $T \in(\Gamma \rightarrow \Lambda)!_{\overrightarrow{\bar{x}}_{\bar{U}}} \cup \overrightarrow{\hat{H}}_{e_{U}}^{+}$and the goal has been proved.

[^16]:    ${ }^{25}$ The fact that $B_{0}$ may involve axioms of associativity without commutativity -for which the number of unifiers may be infinite- may be a problem. In this case, Maude's $B_{0}$-unification algorithm will either find a complete finite set of unifiers, or will return a finite set of such unifiers with an incompleteness warning. In this second case, the NS rule application would have to be undone due to incompleteness. But this second case seems unlikely thanks to two favorable reasons: (1) the unifiers in $\operatorname{Unif}_{B_{0}}\left(f(\vec{v})^{\circ}=f\left(\vec{u}_{i}\right)\right)$ are disjoint unifiers, i.e., no variables are shared between the two unificands; and (2) we may safely assume, without loss

[^17]:    ${ }^{26}$ The net effect is not only that EPS both subsumes ERL and ERR and becomes more powerful: by adding such extra rules to $\overrightarrow{\mathcal{E}}_{U}^{=}$, the ICC simplification rule discussed next, which also performs simplification with equality predicates, also becomes more powerful.
    ${ }^{27}$ More generally, the equality predicate theory $\overrightarrow{\mathcal{E}}_{U}^{=}$can be extended by adding to it conditional rewrite rules that orient inductive theorems of $\mathcal{E}$ or $\mathcal{E}_{U}^{=}$, are executable, and keep $\overrightarrow{\mathcal{E}}_{U}^{=}$operationally terminating. For example, if $c$ and $c^{\prime}$ are different constructors whose sorts belong to the same connected component having a top sort, say, $s$, then the conditional rewrite rule $x=c\left(x_{1}, \ldots, x_{n}\right) \wedge x=c^{\prime}\left(y_{1}, \ldots, y_{m}\right) \rightarrow \perp$, where $x$ has sort $s$ orients an inductively valid lemma, clearly terminates, and can thus be added to $\overrightarrow{\mathcal{E}}_{U}^{=}$. In particular, if $p$ is a Boolean-valued predicate, $p\left(u_{1}, \ldots, u_{n}\right)=$ true $\wedge p\left(u_{1}, \ldots, u_{n}\right)=$ false rewrites to $\perp$.

[^18]:    ${ }^{28}$ For unconditional rules, "narrowing" is meant here in the sense (generalized to the order-sorted case) of narrowing a term with rewrite rules modulo axioms $B$ [40]. For conditional rules, it is meant in the sense of order-sorted constrained narrowing modulo axioms $B$ proposed in [12]. The condition $\Gamma_{i}$ of rule [i] is then carried along as a constraint, which in the NI inference rule is then added to the premise of subgoal $i, j$-after instantiating it by the associated substitutionfor each $j \in J_{i}$.

[^19]:    ${ }^{29}$ In general, there may exist more than one position $p$ (and more than one $\gamma$ ) at which $w={ }_{B_{0}} u \theta \gamma$ occurs in the goal multiclause. In such a case, an implementation of this rule should present the various matches and positions found to let the user choose the desired ones.

[^20]:    ${ }^{30}$ For the sake of simplicity, we here use true and false instead of $T$ and $\perp$ for the truth values of $\quad=\quad$, i.e., we do not keep a renamed copy of the Booleans with $\top$ and $\perp$ as its truth values.

[^21]:    ${ }^{31}$ For the sake of simplicity, we here use true and false instead of $T$ and $\perp$ for the truth values of _ = ( see Footnote 30).

[^22]:    ${ }^{32}$ ACL2 is of course a general purpose inductive theorem prover. The main difference with equational theorem provers in the broader sense is that they support any user-defined algebraic signatures. Therefore, they can directly represent any algebraic data types, whereas in ACL2 such data types are represented indirectly, by encoding them as LISP data structures.
    ${ }^{33}$ The GSI rule could also be automated; but this will probably require more complex heuristics.

[^23]:    ${ }^{34}$ The equations defining the equality predicates are not needed here: we only need the extend signature to represent formulas as terms.
